The "ſpiritus tenuior," or "weaker ſpirit," of the Lond. Ph.; the "diluted alcohol," the "ſpiritus vinoſus tenuior ſive dilutus" of Edinb. Ph.; and "ſpiritus vinoſus tenuior" of Dub. Ph., or "proof ſpirit," is merely rectified ſpirit diluted with a certain proportion of water. According to the London and Dublin colleges, its ſpecific gravity ſhould be to that of diſtilled water, as 930 to 1000; while the Edinburgh college orders it of the gravity of 935. The former may be formed by mixing four parts by meaſure of rectified ſpirit with three of water, and contains 44 parts of pure alcohol, and 55 of water, in 100 parts; the latter is obtained from equal parts of rectified ſpirit and water, and contains 42 of pure alcohol, and 58 of water, in 100 parts. Alcohol, diluted to the degree of proof-ſpirit, is ſtill a very powerful diffuſible ſtimulant, and too ſtrong for internal uſe. Externally applied, it is recommended in burns; to reſtrain bleeding in paſſive hæmorrhagies; and as a friction or fomentation to relieve muſcular pains; and in a more diluted ſtate it forms a good collyrium in the latter ſtage of ophthalmia. Proof-ſpirit diluted with water is employed as a remedy in the form of tinctures and ſpirits; and the ardent ſpirits in common uſe may be regarded as nearly of the ſame nature. Theſe taken in moderation, increaſe the general excitement, communicate additional energy to the muſcular fibres, ſtrengthen the ſtomach, and exhilarate the mind. Hence they are often and advantageouſly uſed in caſes of debility and low typhoid fevers, in which the uſe of wine is indicated; and in habits diſpoſed to create acidity, they are even preferable to wine; ſome of them, particularly brandy, proving gratefully ſtomachic, when wine is nauſeated and rejected. As an article, however, of daily or dietetical uſe, particularly if taken in immoderate doſes, or long continued, ardent ſpirits, beſides being the ſource of much moral evil, and debaſing the human character nearly to a level with that of brutes, are apt to occaſion diſeaſe, and are commonly the origin of dyſpepſia, hypochondriaſis, and hepatic and viſceral obſtructions. The hurtful effects of ardent ſpirits, however, are obviated in a conſiderable degree by diluting them with water, and adding lemon-juice and ſugar to the mixture, ſo as to form what is generally known by the name of punch. Although all the varieties of ardent ſpirits may be regarded as diluted alcohol, yet each has a peculiar operation: thus, brandy is ſimply cordial and ſtomachic; rum, heating and ſudorific; gin and whiſky, diuretic; and arrack, ſtyptic, heating and narcotic, and ill adapted to European conſtitutions.

Vinous ſpirits, therefore, in ſmall quantity, and properly diluted, may be applied to uſeful purpoſes in the relieving of ſome diſorders; whilſt in larger ones, or imprudently continued, they act as a poiſon of a particular kind. The moderate uſe of them is moſt ſerviceable to thoſe who are expoſed to heat and moiſture, to corrupted air, or to other cauſes of colliquative and putrid diſeaſes; and they are the moſt pernicious in oppoſite circumſtances, and to thoſe who are afflicted with hyſterical and hypochondriacal complaints: for whatever temporary relief theſe ſpirituous cordials may afford in the lowneſſes to which hyſterical and hypochondriacal perſons are ſubject, there are none, as Dr. Pemberton obſerves, who feel ſo ſoon the ill effects ariſing from the habitual uſe of them. Lewis's Mat. Med.

The power of brandy, or any thing of this kind, in killing worms, is evident from this, that the children of the people in the northern iſlands of Scotland, who are accuſtomed from their infancy to drink that coarſe ſort of brandy which they call aqua vitæ, never are troubled with worms. It is a dangerous practice to uſe brandy in this general manner, but on ſome occaſions it may be very ſerviceable. Philoſ. Tranſ. N° 233.

SPIRITS, *Laws relating to Foreign and Britiſh.* By a variety of ſtatutes, which it would be too tedious here to enumerate, duties both permanent and temporary, of the cuſtoms and the exciſe, have been impoſed on brandy, rum, arquebuſade, geneva, arrack, and ſpirits, the amount of which is very conſiderable in proportion to the original price. By 43 Geo. III. c. 69. (ſched. A), and 43 Geo. III. c. 81. ſeveral duties are impoſed upon ſpirits imported; but by 49 Geo. III. c. 98. ſeveral duties of cuſtoms are impoſed: the ſaid duties are payable by the importer, before landing. If any perſon ſhall land any French brandy, before the duty be paid or ſecured, or without licence from the proper officer, and conceal the ſame when landed, he and his aider ſhall not only forfeit the ſame, but alſo double value; and if any officer of the cuſtoms or exciſe ſhall connive at it, he ſhall forfeit 500*l.*, and be incapable of holding any office in the revenue. (1 Ann. ſtat. 2. c. 14.) The officers of exciſe may go on board any ſhip and ſearch, as officers of the cuſtoms may do, for any exciſeable liquors, and ſeize ſuch as ſhall be forfeited, and ſuch as ſhall be unſhipped before entry and payment of the duties, together with the caſks and other package. (11 Geo. I. c. 30.) Any officer of the exciſe may ſearch for concealed foreign ſpirits, and ſeize, &c.; and the penalty of obſtruction is a forfeiture of 100*l.* By a general clauſe in 8 Geo. I. c. 18. all brandy, arrack, rum, ſpirits, and ſtrong waters, and all foreign exciſeable liquors, forfeited, together with the caſks and package, may be ſeized by any officer of the cuſtoms or exciſe, or perſons deputed from the lord treaſurer, or under-treaſurer, or by ſpecial commiſſion under the great or privy ſeal, and no other perſon; and the penalty of obſtruction is 40*l.* If any foreign brandy, arrack, rum, or ſtrong waters, or ſpirits of any kind, ſhall be imported in any veſſel of 100 tons burden, or under, (except for the uſe of ſeamen, not exceeding two gallons each,) ſuch veſſel, with its tackle, and alſo the ſpirits, ſhall be forfeited (5 Geo. III. c. 43.): except rum or other ſpirits of the growth and manufacture of the Britiſh ſugar plantations, which may be imported in any veſſel of not leſs burden than 70 tons. (6 Geo. III. c. 46.) If any veſſel of 50 tons, or under, partly or fully laden with brandy, be at anchor or within two leagues of the ſhore, and not proceeding on her voyage, if wind and weather permit, ſuch veſſel may be compelled by the commander of any man of war, or armed ſloop appointed to guard the coaſt, or the commander of any veſſel in the ſervice of the cuſtoms, to come into port; and the caſe is the ſame with ſhips hovering near the coaſts. (6 Geo. I. c. 21.) If any veſſel come from foreign parts, and have on board any foreign brandy or ſpirits, in caſks under ſix gallons, (except for the uſe of ſeamen, not exceeding two gallons each,) ſhall be found at anchor, &c. as in the former caſe, all ſuch ſpirits, with the caſks and package, or value, ſhall be forfeited, and the ſame may be ſeized, or value ſued for by the officers; and if the veſſel do not exceed 50 tons in burden, the ſaid veſſel, with her tackle and furniture, ſhall be forfeited: and if any perſon, having charge of the veſſel, ſhall ſuffer any brandy to be put into lighters or boats, in order to be landed, he ſhall, beſides other penalties, ſuffer ſix months' impriſonment. No brandy ſhall be imported in any veſſel not containing 60 gallons at the leaſt, on pain of forfeiting the ſame, or value. (4 W. c. 5.) And no geneva or rum ſhall be imported in any veſſel or caſk, not containing 60 gallons at leaſt, (except for the uſe of ſeamen, not exceeding two gallons each,) on pain of forfeiture. (5 Geo. III. c. 43.) If any officer ſhall find any increaſe of rum or ſpirits, (except ſuch as have been imported and lodged in a warehouſe, according to law,) above the quantity found on the laſt ſurvey, or any decreaſe, (beyond the quantity legally delivered or allowed for leakage,) the proprietor or importer ſhall forfeit 500*l.*; and opening the warehouſe, except in the preſence of the warehouſe-keeper or exciſe officer, incurs a forfeiture of 500*l.* If any rum or ſpirits remain in the warehouſe above twelve calendar months (6 Geo. III. c. 47.), without paying the duty, the commiſſioners of exciſe may ſell them by auction, and pay the duty and charges, transferring the overplus to the proprietor or importer. A permit ſhall be obtained for removal of the quantity ſold; nor ſhall any liquor, exceeding one gallon, be carried away without ſuch permit, on pain of forfeiting the ſame, with the caſks and veſſels. If the liquor be not removed, and the permit not returned, the perſon that took it out ſhall forfeit treble value. No perſon ſhall receive a permit, without direction in writing of the perſon (or his ſervant) from whoſe ſtock the goods are to be removed, on pain of 50*l.*; and in default of payment, three months' impriſonment. No foreign ſpirits, although under one gallon, ſhall be received into the cuſtody of any retailer, without a permit, ſignifying that the duties were paid, or that they had been condemned, on pain of forfeiting the ſame. (8 Geo. I. c. 18.) No ſeller or dealer ſhall be allowed to take out more than one permit in one day; provided that ſeveral permits may be taken out, and caſks containing foreign ſpirituous liquors ſent to the ſame perſons the ſame day, ſo that each caſk may be ſent under different permits, and by different conveyances; and provided dealers ſhall not be prevented from ſending with one permit by one and the ſame conveyance any number of caſks, containing 60 gallons each, or upwards, of the ſame kind. Foreign ſpirits, not being caſks of 60 gallons, or upwards, ſhall not be removed, unleſs at the following times; that is, from September 29th to March 25th, yearly, between the hours of ſeven in the morning and five in the evening; and from March 25th to September 29th, between the hours of five and ſeven, (except the ſame is carrying by a known common ſtage-coach, waggon, or other ſtage carriage, uſually travelling out of theſe hours,) on pain of forfeiture, with or without a permit. (23 Geo. III. c. 70.) No foreign ſpirits more than 60 gallons ſhall be brought to London by one permit, or one conveyance, at the ſame time, from any part of England by land or water, (except by Graveſend, in the ordinary courſe of commerce,) on pain of being ſeized and forfeited. (26 Geo. III. c. 73.) If any perſon ſhall counterfeit a permit, or give or receive any falſe permit, or alter any granted by the proper officer, he ſhall forfeit 500*l.* 23 Geo. III. c. 70.

For the conditions, regulations, and reſtrictions, under which rum imported from the Weſt Indies may be ſecured in warehouſes, without payment of duty, ſee 43 Geo. III. c. 132. 45 Geo. III. c. 87. 46 Geo. III. c. 137. and 48 Geo. III. c. 126; and for thoſe under which brandy, geneva, and other ſpirits, may be ſecured in warehouſes, without payment of duty, ſee 43 Geo. III. c. 132. 45 Geo. III. c. 87. 46 Geo. III. c. 137. and 48 Geo. III. c. 126. For other laws and regulations, ſee CUSTOMS, DISTILLER, EXCISE, SMUGGLING, and WINE.

SPIRIT *of Ammonia*, in the *Materia Medica*, is prepared, according to the directions of the Lond. Ph., by mixing two pints of rectified ſpirit with a pint of ſolution of ammonia. The "ammoniated alcohol," formerly *ſpirit of ammonia*, of the Ed. Ph., conſiſts of 32 oz. of alcohol (835), 12 oz. of lime recently burnt, and 8 oz. of muriate of ammonia; and is prepared in the ſame manner as water of ammonia. (See AMMONIA.) The *ſpirit of ammonia* of the Dub. Ph. is prepared by mixing three pints of proof-ſpirit, 4 oz. of muriate of ammonia, and 6 oz. of potaſhes; and diſtilling, with a moderate heat, two pints. This ſpirit, properly prepared, has the pungent odour and acrid taſte of ammonia, with which it coincides in its medicinal properties. (See AMMONIACAL *Preparations.*) It is chiefly uſed for pharmaceutical purpoſes. The officinal preparations are "ſpiritus ammoniæ compoſitus," "ſpiritus ammoniæ fœtidus," "tinctura caſtorei compoſita," "tinctura guaiaci compoſita," and "tinctura opii compoſita."

SPIRIT *of Ammonia, Aromatic*, is prepared, according to the Lond. Ph., by mixing two pints of ſpirit of ammonia with oil of lemon and oil of cloves, of each two fluid-drachms. The "aromatic ammoniated alcohol," formerly *aromatic ſpirit of ammonia*, of the Edinb. Ph., is compoſed of 8 oz. of ammoniated alcohol, 1½ drachm of volatile oil of roſemary, and a drachm of volatile oil of lemons, which are mixed ſo as to diſſolve the oils. The *aromatic ſpirit of ammonia* of the Dub. Ph. is formed by digeſting two pints of ſpirit of ammonia, two drachms of eſſential oil of lemons, and half an ounce of bruiſed nutmegs, in a covered veſſel for three days, frequently ſhaking the veſſel; and then diſtilling a pound and a half. This ſpirit is an uſeful ſtimulant in languors, and flatulent colic; and the oils render it more grateful to the ſtomach than the ſimple ſpirit of ammonia. The doſe is from fʒſs to fʒj, in any convenient vehicle. The officinal preparations are "tinctura guaiaci ammoniata," and "tinctura valerianæ ammoniata."

SPIRIT *of Ammonia, Fœtid*, is prepared, according to the Lond. and Dub. Ph., by macerating two pints of ſpirit of ammonia, and 2 oz. of aſſafœtida (1½ oz. Dub.), for 12 hours (for three days, in a covered veſſel, with frequent agitation, Dub.); and then by a gentle fire diſtilling a pint and a half into a cold receiver. The "fœtid ammoniated alcohol," formerly *fœtid ſpirit of ammonia*, of the Edinb. Ph., is prepared by digeſting 8 oz. of ammoniated alcohol, and ½ oz. of aſſafœtida, in a cloſe veſſel for 12 hours, and then diſtilling 8 oz. by the heat of boiling water. The medicinal properties of this ſpirit, and the doſe, are the ſame with thoſe of the preceding. It acquires colour from age.

SPIRIT *of Ammonia, Succinated*, of the Lond. Ph., is prepared by macerating three drachms of maſtich in nine fluid-drachms of alcohol, ſo that it may be diſſolved, and pouring off the clear tincture; then adding fourteen minims of oil of lavender, four minims of oil of amber, and ten fluid-ounces of ſolution of ammonia, and mixing them by agitation. This ſpirit is employed as a ſtimulant and antiſpaſmodic, in the ſame caſes as the oil of amber, and has been uſed with ſucceſs in India againſt the bite of the rattle-ſnake. The doſe is from ♏x to fʒſs, in any convenient vehicle. See AMBER.

SPIRIT *of Aniſe-ſeed* of the Lond. Ph. is formed by macerating for 24 hours half a pound of aniſe-ſeeds bruiſed, a gallon of proof-ſpirit, and a ſufficient quantity of water to prevent empyreuma, and diſtilling by a gentle fire. The *compound ſpirit of aniſe-ſeed* of the Dub. Ph. is obtained by diſtilling one gallon from aniſe-ſeeds and angelica ſeeds bruiſed, of each half a pound, a gallon of proof-ſpirit, and water ſufficient to prevent empyreuma. In flatulent colic, and ſimilar affections, theſe are pleaſant carminatives. The doſe is from fʒſs to fʒiv, in water.

SPIRIT *of Horſe-radiſh, Compound*, "ſpiritus armoraciæ compoſitus," of the Lond. Ph., is prepared by macerating freſh horſe-radiſh ſliced and orange-peel dried, of each a pound, half an ounce of nutmegs bruiſed, a gallon of proof-ſpirit, and water ſufficient to prevent empyreuma, for 24 hours, and diſtilling a gallon by a gentle fire. (See COCHLEARIA.) The "compoſitus ſpiritus raphani," of the Dub. Ph., is formed by diſtilling two gallons from horſe-radiſh dried and peel of Seville oranges, of each two pounds, four pounds of freſh garden ſcurvy-graſs, one ounce of nutmegs bruiſed, two gallons of proof-ſpirit, and water ſufficient to prevent empyreuma. Theſe ſpirits, which were formerly uſed as antiſcorbutics, are now held in little eſtimation in that intention. They are chiefly uſed in dropſies, attended with much debility. The doſe is from fʒj to fʒiv, combined with infuſion of fox-glove or juniper-berries.

SPIRIT *of Camphor* of the Lond. Ph. is prepared by mixing four ounces of camphor with two pints of rectified ſpirit, that the camphor may be diſſolved. The "tincture of camphor," commonly called the "camphorated vinous ſpirit," is obtained by mixing one ounce of camphor with one pound of alcohol (ſp. gr. 835), ſo that the camphor may be diſſolved. It may be alſo made with double or triple the quantity of camphor. This ſpirit is too ſtrong to be given internally; and if water be mixed with it, the camphor is ſeparated. It is an uſeful ſtimulant and diſcutient application to chilblains, and in chronic rheumatiſm, paralytic numbneſs, and gangrene. See CAMPHOR.

SPIRIT *of Carraway* of the Lond. and Dub. Ph. is obtained by macerating a pound and a half (half a pound, Dub.) of carraway ſeeds bruiſed in a gallon of proof-ſpirit, and water ſufficient to prevent empyreuma, for 24 hours, and diſtilling a gallon by a gentle fire. The *ſpirit of carraway* of the Edinb. Ph. is prepared by macerating half a pound of carraway ſeeds bruiſed in nine pounds of proof-ſpirit, for two days in a cloſe veſſel, adding water enough to prevent empyreuma, and diſtilling nine pounds. This ſpirit is an uſeful carminative, and an adjunct to griping purgatives. See CARUM.

SPIRIT *of Cinnamon* of the Lond. and Dub. Ph. is prepared by macerating one pound of cinnamon bark bruiſed in a gallon of proof-ſpirit, and water ſufficient to prevent empyreuma, for 24 hours, and diſtilling a gallon by a gentle fire. The *ſpirit of cinnamon*, "ſpiritus corticis lauri cinnamomi," of the Edinb. Ph., is prepared with a pound of cinnamon bark, in the ſame manner as the ſpirit of carraway.

This ſpirit is an agreeable cordial in diſeaſes attended with much languor and debility. The doſe is from fʒj to fʒiv, in any ſuitable vehicle. The officinal preparation is "infuſum digitalis." See CINNAMON.

SPIRIT, *Coal.* See COAL.

SPIRIT *of Sulphuric Ether* of the Lond. Ph. is obtained by mixing half a pint of ſulphuric ether (ſee ETHER) with a pint of rectified ſpirit. The "ſulphuric ether with alcohol," of the Edinb. Ph., is prepared by mixing one part of ſulphuric ether with two parts of alcohol. The ſpecific gravity of this mixture is .816. It may be uſed for the ſame purpoſes as the ether, but it is much leſs active. The doſe is from fʒj to fʒiij. An uſeful gargle for ſlight inflammation of the fauces is prepared by adding fʒj of this ſpirit to f℥vi of boiling water, ſweetened with fʒiv of ſyrup of marſh-mallows. The ſulphuric ether, of which this is an officinal preparation, is ſtimulant, narcotic, and antiſpaſmodic. In its operation it reſembles alcohol, but is more diffuſible, and its effects are leſs permanent. It is beneficially employed as a cordial in typhoid and low fevers, particularly when nauſea, ſubſultus tendinum, and other ſpaſmodic ſymptoms are preſent. As an antiſpaſmodic, it relieves the paroxyſm of ſpaſmodic aſthma, whether it be taken into the ſtomach, or its vapour only be inhaled into the lungs; in which latter form it is alſo uſeful in ſimple dyſpnœa and in catarrh. It is employed with advantage in hyſteria, tetanus, cramp of the ſtomach, hiccough, and in cholera morbus to check the vomiting; and alſo allays the violence of ſea-ſickneſs. The uſual doſe of ſulphuric ether is from fʒſs to fʒij; but it has been given in much larger doſes with the moſt beneficial effects; and in all caſes, the doſe muſt be repeated at ſhort intervals, to produce the full effect of the remedy. As an external application, ether acts either as a ſtimulant or a refrigerant, according to the mode in which it is applied. The firſt takes place when it is prevented from evaporating, by being confined over the ſpot to which it is applied; in which caſe it often proves uſeful in relieving head-ache, and other muſcular pains: and from its refrigerant effect produced by its rapid evaporation, it is applied to burns, and to aſſiſt in the reduction of ſtrangulated hernia. It has produced, ſays Thomſon (Lond. Diſp.), almoſt immediate relief in ear-ache, when dropped into the external meatus.

SPIRIT *of Ether, Aromatic,* of the Lond. Ph., is obtained by macerating three drachms of cinnamon bark bruiſed, a drachm and a half of cardamom ſeeds powdered, long pepper powdered and ginger-root ſliced, of each a drachm, in a pint of ſpirit of ſulphuric ether, for 14 days, in a ſtopped glaſs-bottle, and ſtraining. The "aromatic ſulphuric ether with alcohol," of the Edinb. Ph., is made with the ſame aromatics, and in the ſame manner as the compound tincture of cinnamon, except that ſulphuric ether with alcohol is employed inſtead of proof-ſpirit. The medicinal properties of theſe preparations are the ſame with thoſe of the former; the aromatics rendering them in a ſlight degree more grateful.

SPIRIT, *Ethereal, of Frobenius, Spiritus Etherius Frobenii,* a name given by Frobenius, and others, to a liquor famous for its extreme volatility, and many other qualities; for which ſee *Sulphuric* ETHER.

The uſe of this liquor in medicine is now well known: as a very thin and volatile inflammable matter, it acts powerfully on the nervous ſyſtem. Frederic Hoffman was one of the firſt who employed it as a ſedative and antiſpaſmodic. See LIQUOR *Mineralis Anodynus,* and SPIRIT *of Ether,* infra.

It is now often preſcribed ſingly, in the doſe of ſeven or eight drops upon a bit of ſugar, which is to be eat, or to be diſſolved in ſome proper liquor, and drank. It is given in flatulent colics, obſtinate hiccoughs, convulſive hyſterical affections, and other diſorders of this kind. This ether is ſaid to take ſpots of greaſe from ſilk, without affecting their colours.

We have ſeveral curious obſervations on this ether of Frobenius by Mr. Groſſe, who has deſcribed three different methods of making it in the Memoirs of the Academy of Sciences, for the year 1734.

SPIRIT *of Ether, Compound,* of the Lond. Ph., is prepared by mixing a pint of ſpirit of ſulphuric ether with two fluid-drachms of ethereal oil. (See *Sulphuric* ETHER.) This is intended as a ſubſtitute for the anodyne liquor of Hoffman (ſee the preceding article); for, beſides being ſtimulant and antiſpaſmodic, it is ſuppoſed to poſſeſs anodyne properties. It is an uſeful addition to tincture of opium, when given for the purpoſe of procuring ſleep; and it often prevents the opium from exciting the nauſea which it is apt to produce in ſome habits. The doſe is from fʒſs to fʒij, in any appropriate vehicle.

SPIRIT *of Juniper, Compound,* of the Lond., Dub., and Edinb. Ph., is prepared by macerating one pound of juniper-berries bruiſed, carraway ſeeds and fennel ſeeds bruiſed, of each an ounce and a half, in a gallon (nine pounds, Edinb.) of proof-ſpirit, for 24 hours (two days, Edinb. and Dub.); and then diſtilling a gallon (nine pounds, Edinb.) by a gentle heat. This ſpirit is a grateful and uſeful addition to infuſions of fox-glove, and other diuretics, in dropſy. See JUNIPERUS.

SPIRIT *of Lavender.* See LAVANDULA.

SPIRIT *of Libanus, Smoking.* See LIQUOR.

SPIRIT *of Malt.* See MALT-*Diſtillery.*

SIPRIT *of Mindererus.* See ACETITE *of Ammonia,* LIQUOR, and VINEGAR.

SPIRIT, *Moloſſes.* See MOLOSSES-*Spirit.*

SPIRIT *of Nitre.* See NITRIC *Acid,* and *Nitrat* POTASSÆ.

SPIRIT *of Nitric Ether* of the Lond. Ph. is obtained by taking two pints of rectified ſpirit, and three ounces (by weight) of nitric acid. Add the acid gradually to the ſpirit, and mix them, taking care that the temperature, during the mixture, does not exceed 120°; then diſtil, by a gentle heat, 26 fluid-ounces. *Spirit of nitrous ether* of the Edinb. Ph. is prepared by pouring three pounds of alcohol into a large phial placed in a veſſel full of cold water, and adding one pound of nitrous acid gradually, with frequent agitation. Slightly cork the phial, and place it in a cool place for ſeven days; then diſtil the liquor, by the heat of boiling water, into a receiver kept cool with ſnow or water, as long as any ſpirit comes over. The *nitrous ethereal ſpirit* of the Dub. Ph. is prepared in the following manner: Add to the matter which remains after the diſtillation of nitrous ether, the rectified ſpirit of wine, employed in that operation for condenſing the elaſtic vapour, and diſtil to dryneſs, with the greater heat of a water-bath. Mix the diſtilled liquor with the alkaline liquor which remains after the ſeparation of the nitrous ether, and alſo add as much dry ſubcarbonate of kali as ſhall be ſufficient to ſaturate the predominant acid; which is to be determined by the teſt of litmus. Laſtly, diſtil by the medium heat of a water-bath, as long as any fluid comes over. The ſpecific gravity of this liquor is to that of diſtilled water, as 850 to 1000. The ſpirit of nitric ether, as procured by the London or Edinburgh proceſs, has an extremely fragrant odour, and a pungent acidulous taſte. It is very volatile and inflammable, ſoluble in water and alcohol, and ſtrikes a deep olive with ſolution of green ſulphate of iron. See *Nitrous* ETHER.

Spirit of nitric ether is refrigerant, diuretic, and antiſpaſmodic. It has been long known and uſed, under the title of "ſweet ſpirit of nitre," as a grateful refrigerant, and for quenching thirſt in febrile affections; for which purpoſe the doſe is from ♏xx to ♏xl, given in a cupful of water, or any other appropriate vehicle. In larger doſes it acts as a gentle ſtimulant to the ſtomach, relieving nauſea and flatulence; and alſo determines to the kidnies, increaſing the flow of urine; on which account it is advantageouſly preſcribed as an auxiliary to other diuretics in dropſical complaints. The dulcified ſpirit of nitre is added by drops to potions and juleps, till it has given them an agreeable acidity.

It is alſo much uſed by our diſtillers to give a vinoſity to thoſe ſpirits, whoſe natural flavour of that kind they have deſtroyed by the improper uſe of alkaline ſalts in the rectifications. Nothing can be more proper for this purpoſe than this ſpirit, as it really gives the brandy-flavour, and is not at all prejudicial to health, but very well falls in with the nature of the ſpirit, and promotes its medicinal properties as a diuretic, deobſtruent, and lithontriptic.

It has been ſuggeſted, that the method of making it for this purpoſe is improveable, by uſing in the preparation a ſpirit of wine impregnated with ſome fine flavoured ingredient, which has not much oil, for acids do not readily mix where there is much oil.

In the preparation of this dulcified ſpirit of nitre, the longer it ſtands in digeſtion with the ſpirit of wine, the milder it grows; and by the ſame means alſo, the violently corroſive oil of vitriol may be ſo blunted, as to be rendered ſcarcely perceptible to the taſte. In fine, it has been ſaid that a ſpiritus nitri dulcis may be made, by a ſlow digeſtion, greatly ſuperior to that commonly uſed, and of ſo fixed a nature, that it will not be ſubject to have its flavour fly off from the ſpirit with which it is mixed, any ſooner than the native vinoſity of brandy will of itſelf fly off from that ſpirit, as it always will in time. A proper care in the preparation of this acid might free the diſtillers from that troubleſome neceſſity they are under of adding their ſpirit of nitre, juſt before they ſend their goods away, for fear the flavour ſhould be loſt before the ſpirit is wholly uſed, and ſo the ſophiſtication be found out. There is no fixing any certain proportion in which the acid is to be mixed with the ſpirit, but in general it is beſt not to over-do it; for though it will give an agreeable vinoſity to any tolerable clean ſpirit, the perſon will be much deceived who attempts to drow the bad flavour of a foul one by it. Shaw's Eſſay on Diſtillery.

Mr. Woulfe deſcribes an apparatus by which *nitrous ether* (in the article under ETHER) may be expeditiouſly obtained by diſtillation, with the heat only occaſioned by mixing together the nitrous acid and the ſpirit of wine. This diſtillation is performed in a matraſs with a high neck, to which is fitted a head with a ſpout, communicating with the receiver by means of a long tube. The vapours that are not condenſed in this receiver, or in a bottle joined to a ſpout in its bottom, are conveyed from the receiver through a bent tube into ſpirit of wine contained in a bottle. If any vapours paſs uncondenſed through this ſpirit of wine, they are conveyed through another bent tube into more ſpirit of wine contained in another bottle. The liquor collected in the bottle annexed to the receiver, being ſlowly rectified with ſlaked lime, furniſhes very fine ether. The ſpirit of wine in which the vapours were condenſed, contains ſo much ether, that this fluid may be ſeparated from the ſpirit by adding water. This ſpirit of wine is by the operation changed into good dulcified ſpirit of nitre. Phil. Tranſ. vol. lvii. art. 59.

SPIRIT *of Sal Ammoniac.* See AMMONIACAL *Preparations.*

SPIRIT *of Salt.* See MURIATIC *Acid.*

SPIRIT *of Sulphur*, or *of Vitriol.* See SULPHURIC *Acid.*

SPIRIT *of Wine.* See ALCOHOL and WINE.

SPIRIT is alſo uſed for any incorporeal being, or intelligence. In which ſenſe God is ſaid to be a ſpirit, angels are ſpirits; and the devil is an evil ſpirit.

In this ſenſe the human ſoul is alſo called a ſpirit, from its thinking and reflecting powers, which cannot be conceived to reſide in any thing material. See SOUL.

F. Malebranche obſerves, it is extremely difficult to conceive what it is that ſhould make the communication between the body and the ſpirit; for if the ſpirit have no material parts, it cannot move the body. But the argument muſt be falſe ſomehow or other; for we believe that God can move bodies, and yet do we not attribute any material parts to him.

SPIRIT, in *Theology*, is uſed, by way of eminence, for the third perſon in the Holy Trinity, called *the Spirit, the Holy Spirit*, or *Holy Ghoſt.*

Concerning the nature and even the perſonality of the Holy Spirit, very different opinions have been entertained by theological writers, both ancient and modern. It has been ſaid, indeed, that no mention occurs of any difference of opinion on this ſubject, that attracted any notice, till after the commencement of the Arian controverſy, and even till after the council of Nice. It has been alſo aſſerted, that even after the riſe of the Arian controverſy, many perſons expreſſed themſelves concerning the Spirit as if it had no proper divinity, at leaſt of a perſonal nature, without cenſure; and that this could not have been the caſe, if it had been the uniform doctrine of the orthodox, that the Holy Spirit was a proper *divine perſon*, equal to the Son, or the Father. Clement, one of the apoſtolical fathers, makes no particular mention of the Holy Spirit. Ignatius, allowing his epiſtle to the Epheſians to be genuine, ſeems to have conſidered the Holy Spirit rather as a "power" than as a "perſon." Juſtin Martyr ſays but little concerning the Holy Spirit; nor is it eaſy to conclude what was his real opinion. But ſome have imagined that he regarded him as a created being, ſince he repreſents him as inferior to Chriſt. Irenæus ſeems to have conſidered the Holy Spirit as a divine influence, and no proper perſon; calling him, in reference to the words of Iſaiah (ch. lxi. 1.), the unction. Athenagoras conſidered the Holy Spirit as an efflux from the Deity. Tertullian ſeems to have thought, that the Holy Spirit was derived from Chriſt, in the ſame manner as Chriſt was derived from God, that is, by a kind of prolation. Novatian, who was as orthodox in his notions with regard to the Trinity as any perſon in his age, could not believe in the divinity of the Holy Spirit, whom he repreſents as inferior to the Son, whom he alſo makes inferior to the Father. Lactantius is complained of for not mentioning the Holy Spirit, and for denying his perſonality. Dionyſius of Alexandria is cenſured by Baſil for not admitting the divinity of the Holy Spirit, and reducing him to the rank of a created being. Hilary alſo ſeems to have conſidered the Spirit as a divine influence. After the council of Nice, the ſentiments and language of the fathers appear to have undergone a material change. Athanaſius contended ſtrenuouſly and effectually, not only for the divinity of Chriſt, and his conſubſtantiality with the Father, but alſo in behalf of that of the Holy Spirit, whoſe divinity was denied by Macedonius. Being in Egypt when this hereſy prevailed, he procured a ſynod to be called, at which he attended, and where the Holy Spirit was, for the firſt time, decreed to be conſubſtantial with the Father and the Son. Soon after this, the divinity of the Holy Spirit was more ſolemnly determined at a council held in Conſtantinople, and from that time it was decreed no leſs heretical to deny the divinity of the Spirit, than that of the Son.

At this time the doctrine of the perfect equality of the Spirit and the Son, as well as that of the Son and the Father, was fully eſtabliſhed; and it was not long before the forms of public worſhip were accommodated to this opinion; for inſtead of the cuſtomary doxology of “Gloria Patri,” Flavianus of Antioch made an alteration, for which purpoſe he is ſaid to have aſſembled a number of monks, and to have firſt chanted out “Glory to the Father, to the Son, and to the Holy Ghoſt.” Whereas, before his time, ſome had ſaid “Glory to the Father through the Son, in the Holy Spirit,” which was the moſt cuſtomary form; and others, “Glory to the Father in the Son, and the Holy Spirit.”

The doctrine avowed and maintained by Athanaſius, was ſupported by the influence of Baſil, the two Gregories, Chryſoſtom, and Cyril of Alexandria. The latter ſays, “the Holy Spirit is the Spirit of the unbegotten God, and comes forth from him, has perſonality and life, and always exiſts, being from that which exiſts.” At this time the doctrine of the inferiority of the Spirit to the Son, and of his having been created by him, was ſeverely reprobated. Baſil maintained, that to deny the divinity of the Holy Spirit, is to be guilty of blaſphemy againſt the Holy Spirit; and Chryſoſtom obſerves, “it cannot be that he who halts with reſpect to the Spirit, can walk upright with reſpect to the Son.” However, though it was admitted, that the Spirit was a divine perſon as well as the Son, and yet, like the Son, not abſolutely underived, there was ſome difficulty in ſettling the mode of his derivation. At length, the term “proceeding” was adopted, as expreſſing the manner of the emiſſion of the Spirit from the fountain of Deity, and was deemed to be different from that of “generation,” which had been appropriated to the Son: nevertheleſs, the difference between the two terms could not be eaſily adjuſted. Auſtin ſays that the Holy Spirit, being the Spirit both of the Father and the Son, proceeds from them both; and this he makes to be the difference between the generation of the Son and the proceſſion of the Spirit. Cyril of Alexandria thought that he had ſome idea of the nature of the proceſſion of the Spirit from the ſubſtance of God, when he ſays, that “Chriſt breathed upon his diſciples, to ſhew that the Holy Spirit proceeds from the divine ſubſtance, as the breath of man proceeds from him.”

In proof of the divinity of the Holy Spirit it has been alleged, that divine names, titles, attributes, works and worſhip, are or ſeem to be aſcribed, in various paſſages of ſcripture, to the Holy Spirit. Many plead that the Holy Spirit is called Jehovah in the Old Teſtament, by comparing Acts, xxviii. 25. with Iſaiah, vi. 9; and Heb. iii. 7—9. with Exod. xvii. 7; Jer. xxxi. 31—34. with Heb. x. 15, 16. In adverting to the firſt of theſe cited paſſages, in which the words ſpoken by God to Iſaiah are by St. Paul ſaid to be ſpoken by the Holy Ghoſt, it has been concluded, that God and the Holy Ghoſt are one and the ſame individual perſon. But in Rev. xi. 43, an inferior angel is introduced as ſpeaking in the perſon of God, and therefore this mode of reaſoning has not been allowed by the oppugners of this doctrine. It is alleged further, that the Holy Spirit is, probably, called God v. 4, to which paſſages ſome add 1 Cor. iii. 16. vi. 19. 2 Cor. iii. 17. Moreover, divine perfections are ſaid to be aſcribed to the Spirit of God; particularly omniſcience, 1 Cor. ii. 10, 11. Iſ. xl. 13, 14; to which ſome add 1 John, ii. 20; — omnipreſence, Pſ. cxxxix. 7. Eph. ii. 17, 18. Rom. viii. 26, 27; — omnipotence, Luke, i. 35. 1 Cor. xii. 11; — eternity, Heb. ix. 14. Again; divine works are aſcribed to the Spirit, Gen. i. 2. Job, xxvi. 13. xxxiii. 4. Pſ. xxxiii. 6. civ. 30, &c. Some perſons likewiſe add thoſe texts in which miracles, inſpiration, and ſaving operations upon the heart of man, are aſcribed to the Spirit. The chief texts produced to prove that divine worſhip is given to the Spirit are, Iſ. vi. 3. compared with v. 9, and Acts, xxviii. 25, &c. Rom. ix. 1. Rev. i. 4. 2 Cor. xiii. 14; and above all, Matth. xxviii. 19. Upon the whole it is alleged, that the bleſſed Spirit is ſpoken of in ſuch a manner, as it cannot be imagined would be uſed in ſpeaking of a mere creature, and, conſequently, muſt be poſſeſſed of a nature properly divine. On the other hand it is maintained, that the proofs taken from the attributes and operations of the Spirit are of no more force than in the caſe of the Son's ſupreme deity; both Son and Spirit, being agents under God at his will, are concerned in his glorious works, and partakers of his power and wiſdom; ſo that it is no wonder if moſt of theſe be aſcribed to the Spirit, but ſtill as to one ſent of God. Moreover, theſe arguments bear leſs evidence in relation to the Holy Spirit, becauſe of the different ideas which the word Spirit ſtands for. The Spirit, and Holy Spirit, very often ſignify not a perſonal Spirit, but the attributes and operative efficacious virtue of God, the energy of his power, wiſdom, and holineſs, exerted in powerful operations, afflatus, and inſpiration. The name of God is never once given to the Spirit, nor is direct worſhip or invocation, prayer or praiſe, glory or dominion, once given to him, in precept or practice, in the New Teſtament; though his communications are wiſhed and prayed for to Chriſtians, 2 Cor. xiii. 14.

The chief controverſy on this head is, whether the ſpirit of God be a perſon in the *philoſophical ſenſe*, or merely a divine *power* or energy. That he is a *perſon*, is argued from his being deſcribed as having underſtanding, 1 Cor. ii. 10, 11; willing, 1 Cor. xii. 11; ſpeaking and ſending meſſengers, Iſ. vi. 8, compared with Acts, xxviii. 25. viii. 19. x. 19, 20. xiii. 1—4. 1 Tim. iv. 1; as Dr. Barrow interprets it, ſending Chriſt, Iſ. xlviii. 16; as pleading, Rom. viii. 26; as being grieved, Iſ. lxiii. 10. Eph. iv. 30; as teaching and reminding, John, xiv. 26; as teſtifying, John, xv. 26; as reproving, John, xvi. 8, &c.; as executing a commiſſion received from God, John, xvi. 13, 14.

Among thoſe who grant the Spirit to be a perſon, it is debated whether he be the ſame philoſophical perſon with the Father, or another diſtinct from him; to ſuppoſe the latter (ſuppoſing him at the ſame time equal with the Father) is making him *another God*. Some, therefore, have repreſented him as a created Spirit, in his own nature inferior both to Father and Son; againſt which the paſſages above enumerated have been ſtrongly urged; as it has alſo been, that the Spirit is never mentioned as a creature called upon to praiſe God, when a large enumeration of ſuch is made. Others conſider him as a created Spirit, (called as one thinks Michael the archangel), ſo united to God, and ſo actuated by him, as by virtue of this union to become capable of ſuch repreſentations and regards as the Son is, though acting in ſome ſubordination to him in the economy of our redemption;—while many others have contented themſelves with aſſerting, that there is only a *political*, *modal*, or *economical* diſtinction, in the perſonality of the Father, Son, and Spirit. Others again have maintained, that the Spirit is a third diſtinction in the Deity; and when he is called a *perſon*, the word is to be taken in ſuch a ſenſe below the philoſophical and above the modal; though what determination is to be affixed to it, they do not more particularly ſay.

Thoſe, and they form a numerous claſs, who aſſert the Spirit to be a divine *power*, plead chiefly the ſenſe of the word in the Old Teſtament, where they ſay it has generally that ſignification: and that it would be abſurd to ſuppoſe, that the idea ſhould be ſo greatly changed, when Chriſt and his apoſtles addreſſed thoſe who had been bred up in the Jewiſh religion, and muſt, therefore, have been uſed to conceive of the Spirit according to the repreſentation made in their ſacred oracles. It is alſo pleaded, that the *pouring out* one *perſon* on another, is both unſcriptural and unintelligible language, but not ſo, if it relates to a divine *power*, influence, or operation. They urge in favour of the explication of the doctrine, Luke, i. 35; and reply to the paſſages of ſcripture above cited, by obſerving, that nothing was more common among the ancients, and more eſpecially the Eaſtern nations, than to repreſent powers, properties, and attributes, by perſonal characters; thus, wiſdom is repreſented as contriving, rejoicing, inviting, pleading, reproving, &c. Prov. i. 20, &c. iii. 13, &c. iv. 6, &c. viii. 1. ix. 1, &c.; charity, as believing, rejoicing, &c. 1 Cor. xiii.; and death, as being plagued, Hoſ. xiii. 4; the ſcripture, as foreſeeing and preaching, Gal. iii. 8; the ſun, as rejoicing, Pſ. xix. 5; a famine, as coming at God's call, 2 Kings, viii. 1; righteouſneſs, as walking before him, compare Pſ. lxxxv. 10—13; and the wind, as willing, John, iii. 6. To thoſe who allege theſe paſſages, it is replied, that none of them come up to the preceding texts; more eſpecially conſidering how frequently the perſonal term ἐκεῖνος is uſed, when ſpoken of the Spirit, and that not merely in poetical, but moſt plain and ſimple diſcourſes, which, indeed, as it might be argued, is neceſſary to render the perſonification complete; but the ſtrongeſt objection againſt this opinion is ſaid to ariſe from the form of baptiſm, and the forementioned John, xvi. 13, 14.

Dr. Lardner examines the different ſenſes in which the words Spirit, Spirit of God, and Holy Ghoſt, are uſed in the Old and New Teſtament; and he finds, 1. That Spirit is in many places equivalent to God himſelf. 2. That it often means the power or wiſdom of God, or his will and command. 3. That it often means an extraordinary gift from God of power, wiſdom, knowledge, and underſtanding. In Heb. ii. 14. gifts of the Holy Ghoſt ſhould be diſtributions of the Holy Ghoſt; an expreſſion plainly declaring, that by the Holy Ghoſt or Holy Spirit were meant thoſe ſpiritual gifts, which came down upon men from heaven immediately, or were communicated in great variety by laying on the hands of the apoſtles. 4. In the epiſtles of the New Teſtament, there are at the beginning and elſewhere wiſhes of peace from God the Father and the Lord Jeſus Chriſt, but none from the Spirit diſtinctly; nor are there any doxologies or aſcriptions of glory to the Spirit diſtinctly, though there are ſeveral ſuch aſcriptions to God and Chriſt, or to God through Chriſt.

But it may be ſaid, as our learned and impartial author ſtates the objections of thoſe who maintain a different opinion, that the Spirit or the Holy Ghoſt is oftentimes ſpoken of as a perſon, and eſpecially in St. John's goſpel. To which he replies, 1. It is not uncommon in the language of ſcripture, as we have already ſtated at large, to perſonalize many things to which we do not aſcribe intelligence; thus, *e. g.* wiſdom is perſonified in the book of Proverbs, and ſin and death in the New Teſtament. 2. There is not in the Acts of the Apoſtles, or in any other book of the New Teſtament, any account of the appearance and manifeſtation of a great agent or perſon after our Saviour's aſcenſion; therefore no ſuch thing was promiſed or intended by our Saviour, nor expected by his apoſtles, who could not but know his meaning. 3. In other texts of ſcripture, and particularly in St. John's goſpel, by the Spirit or Holy Ghoſt is meant a gift, or plentiful effuſion of ſpiritual gifts. 4. Our Saviour himſelf explains what he meant by the Comforter, *i. e.* the divine influence or effuſion of ſpiritual gifts. 5. Our bleſſed Lord, in ſpeaking of this matter, has made uſe of a variety of expreſſions, by attending to which we may clearly diſcern his true meaning, in what he ſays of the Comforter. All which ſeem to ſhew, that by the Spirit is to be underſtood that ſpecial influence, which, in different meaſures and proportions, God vouchſafes to men through Jeſus Chriſt for their own comfort and eſtabliſhment, and for ſpreading the great truths of religion in the world. This power or divine influence, this effuſion of knowledge and other ſpiritual gifts, our Lord calls the Comforter or the Advocate, παρακλητος, as thereby their cauſe would be pleaded with men, and they would be juſtified in preaching boldly in the name of Jeſus Chriſt. This gift, this divine influence, he calls alſo the ſpirit of truth, becauſe by this wonderful influence on their minds, the apoſtles would be led into the knowledge of all the truths of the Goſpel, and would be enabled to teach them to others with perſpicuity. And our Lord ſpeaks of the Spirit's bringing to their remembrance the things which he had ſaid, and of his receiving of his and ſhewing it unto them; becauſe by his miraculous influence upon their minds, thoſe prejudices would be removed, which had obſtructed their clear diſcernment of what Chriſt had ſaid unto them, when he was with them. By the Holy Ghoſt in Matth. xxviii. 19, where we have the form of baptiſm, we are to underſtand the miracles of our Saviour's miniſtry, and likewiſe the miracles wrought by his apoſtles, and the ſpiritual gifts beſtowed upon the apoſtles and other diſciples of Jeſus, and all believers in general, ſoon after our Lord's aſcenſion, and all the miraculous atteſtations of the truth, and divine origin of the doctrine taught by Jeſus Chriſt. On the ſubject of this article, we refer our theological readers to Calamy on the Trinity, Serm. vi. Emlyn's Tracts, vol. ii. Burnet on the Art.—Script. Doctr. of the Trin. Diſſ. v. Watts on the Trin.—Alſo, Chriſt. Doctr. of Trin. Barrow's Works, vol. ii. Clarke on the Trin. part i. ch. 3. part ii. § 3, 4. 19, 20, 21, 22. 28—32. 40—42. 45, 46. 53. Taylor on the Trin. part iii. Owen on the Spirit, l. i. c. 3. Pearſon on the Creed. Dr. Scott's Eſſ. towards a Demonſtr. of the Script. Trin. prop. iii. Lardner's Firſt Poſtſcr. to the Letter on the Logos, apud Works, vol. xi. Prieſtley's Hiſt. of Early Opinions, vol. ii.—Corruptions, vol. i. Doddridge's Lectures.

SPIRIT, *Order of the.* See HOLY *Ghoſt*.

SPIRIT is alſo uſed, amond *Divines*, for the divine power and virtue, and the communication of it to men.

In this ſenſe, the ſpirit is ſaid to have gone out on the face of the deep (Gen. i. 2.), and the prophets to have been poſſeſſed with the ſpirit of God. Providence, in this ſenſe, is that univerſal ſpirit by which God makes all nature to act.

Thus, the holy Virgin is ſaid to have conceived of the Spirit.

Spirit, *Private*, is a term that made a great figure in the controverſies of the two laſt centuries. It ſignifies the particular ſenſe or notion each perſon has of the dogmata of faith, and the truths of religion, as ſuggeſted by his own thoughts, and the perſuaſion he is under with regard to them.

The firſt reformers denying ſtrenuouſly any infallible interpreter of the ſcripture, or any ſettled judge of controverſies, maintained, that every perſon was to interpret and judge of revealed truths by his own light, aſſiſted by the grace of God; and this was what they called *private* ſpirit or *judgment*.

Againſt this, the arguments uſed by the Romaniſts are, that revealed truths being one and the ſame for all believers; the rule God has given us for judging of them, ought to repreſent them to us uniformly, and the ſame; but the private ſpirit informs Luther one way, and Zuinglius another. It divides Oecolampadius, Bucer, Oſiander, &c. And the doctrine it diſcovers to the Confeſſionites, is quite different from that it ſhews the Anabaptiſts and Mennonites, in the very ſame paſſage of ſcripture.

Spirit, *Spiritus*, is alſo uſed, in *Proſody*, to ſignify the greater or leſs degree of breath employed in the pronunciation of the initial Greek vowels, and of the letter ρ.

In ſounding the vowels, we may obſerve every vowel has its ſound by a ſimple conformation of the mouth, in which the breath has little or no concern, as being confined in the arteria aſpera: the ſpirits, or breaths, which are placed on the initial vowels in words, are to denote the force this initial vowel is to have from the breath, when the word is pronounced. If the ſound of this vowel be ſmooth, as all the ſounds of the vowels naturally are, this is termed *ſpiritus lenis*, a mild breath; but if this vowel be to be pronounced with a more vehement expulſion of the air, this is termed *ſpiritus aſper*, or a rough breath, or aſpirate: and when the aſpirate and acute are in the ſame ſyllable, the mark of the breath, in this initial vowel, only ſignifies, that the vowel is to be pronounced with a ſtronger breath than the initial mild vowels; for aſpirates do not alter the tone of any ſyllable, but only ſtrengthen, increaſe, and ſwell the tone.

Spirit-*Level*. See Level.

Spirit-*Room*, in *Ship-Building*, a ſecure apartment built next abaft the after-hold, to contain the ſpirits. See Ship-building.

SPIRITOSO, *con Spirito*, Ital., in *Muſic*, ſeverally imply animation, ſpirit, and fire, in the performance of the movements to which either of theſe terms is prefixed.

SPIRITU SANTO, or *Eſpiritu Santo*, (which ſee,) in *Geography*, a ſea-port of Brazil, in the government of Rio Janeiro, ſituated on the ſouth ſide of a large bay, about three leagues from the ocean, but having neither walls nor fortifications, except a ſmall ruinated caſtle; ſo that its defence conſiſts in the bravery of its inhabitants, who amount to about 900. The port is a ſmall bay, opening to the eaſt, and interſected with many ſmall iſlands. At the top of a mountain, at ſome diſtance from the town, is a large white tower, which the Portugueſe call Noſtra Senhora de Pena, and near it a ſmall church, ſurrounded with a wall. At the foot of the mountain are ſtill to be ſeen a few old houſes, the melancholy remains of a place once called Villa Veja, or the Old City. S. lat. 20° 8′.—Alſo, a town of the iſland of Cuba; 155 miles E.S.E. of Havannah. N. lat. 22° 15′. W. long. 79° 47′.—Alſo, a town of Peru; 8 miles W. of Potoſi.—Alſo, a town of Chili; 60 miles from Coquimbo.—Alſo, a river of Mexico, which runs into the Pacific ocean, N. lat. 23°. W. long. 106° 40′. —Alſo, a town of Mexico, in the province of Mechoacan; 65 miles E.N.E. of Zacatula.—Alſo, a river of Braſil, which runs into the Atlantic, S. lat. 20° 10′.—Alſo, a lake of Eaſt Florida, near the ſouthern extremity.

Spiritu Santo *Bay*, called alſo Tampay bay, and Hillſborough bay, a large bay on the weſt coaſt of Eaſt Florida. N. lat. 28°. W. long. 82° 45′.

Spiritu Santo *Iſlands*, or *Andros*, a chain of iſlands, ſituated to the ſouth-weſt of the Bahamas; the largeſt about 40 miles in length, and eight in breadth. N. lat. 24° to 25° 12′. W. long. 77° to 78° 15′.

SPIRITUAL Friars. See Franciscans.

SPIRITUALITIES of a biſhop, are ſuch profits as ariſe to him from the benefit of his juriſdiction in his dioceſe, and not as a baron of parliament.

Such are thoſe of his viſitations, inſtitutions, ordinations, preſentation-money, &c.

Spiritualities, *Guardian of the*. See Guardian.

SPIRITUALIUM Custos. See Custos.

SPIRITUALIZATION, in *Chemiſtry*, the action of extracting ſpirits from natural bodies. See Spirit.

Spiritualization is an operation that belongs principally to fermented ſalts, and then to fermented juices and liquors; the fermentation rendering the ſpirits volatile and inflammable.

Spirit of wine is ſometimes ſpiritualized to that degree, that upon throwing a quantity into the air, not a drop ſhall fall down; but the whole evaporate, and be loſt.

SPIRITUS. See Spirit.

SPIRKET, in *Rural Economy*, a term applied to a hook to hang any thing upon, as the cart-geer, &c. in ſtables and other places.

SPIRKETTING, in *Ship-Building*, a thick ſtrake, or ſtrakes, wrought withinſide upon the ends of the beams or water-ways. Spirkettings under ports reach from the water-ways to the upper ſide of the lower ſill, which is generally of two ſtrakes, wrought top and butt.

SPIRTING Cucumber, in *Botany*, a ſpecies of *momordica*; which ſee.

SPISE, in *Geography*, a town of Africa, in the kingdom of Ningo, in the interior part of the Gold Coaſt.

SPISSUM, in the *Ancient Muſic*, was uſed to ſignify thoſe two ſmaller conjunct intervals of a tetrachord, which, taken together, were leſs than the third.

The Greek term for this was πυκνον. This happened in the enharmonic, and the three chromatic genera; in each of which, the interval between the hypate and the lichanos, was leſs than the interval between the lichanos and the nete. To the ſpiſſum was oppoſed the non-ſpiſſum, ἄπυκνον, or *rarum*, as Martianus Capella tranſlates it. The ἄπυκνον happened in the two diatonic genera, where the two ſmalleſt intervals were equal to, or greater than the third. They were ſuppoſed equal in the diatonicum molle, and greater in the intenſum. See Genus.

SPIT, *The*, in *Geography*, a ſhoal of the Atlantic, near the coaſt of South Carolina; 15 miles S. of Cape Fear. N. lat. 33° 34′. W. long. 78° 10′.

Spit, in *Agriculture* and *Gardening*, the quantity or depth of earth or mould which the ſpade takes up at once in digging or delving over ground. Thus, this ſort of work is performed to one, two, or more ſpits deep, according to circumſtances, and the nature of the ſoil and crops.

Spit-*Dung*, that ſort of dung manure which has undergone complete fermentation or putrefaction, and is reduced into a ſomewhat earthy ſtate, ſo as to be dug or taken up by the ſpade or ſhovel in a ſort of ſpit manner.

Spit-*Shovel*, that ſort of tool of the ſhovel kind which is employed in digging out or ſhovelling up ſuch dung, or other matters, as are in a reduced earthy condition. And the term is alſo ſometimes applied to it when uſed in taking up grain for the purpoſe of having it cleaned or removed into another ſituation.

SPITAL, in *Geography*, a town of Auſtria; 6 miles S. of Steyr.—Alſo, a town of Spain, in Catalonia, near the coaſt of the Mediterranean; 22 miles N.E. of Tortoſa.—Alſo, a town of the duchy of Stiria; 5 miles E. of Muertzenſchlag.—Alſo, a town of the duchy of Carinthia, on the Liſer, about a mile from the Drave; 8 miles E. of Saxenburg.

SPITHEAD, a ſpacious reach in the Britiſh Channel, about mid-way between the ſouthern coaſt of Hampſhire and the Iſle of Wight. It directly faces the mouth of Portſmouth harbour, and is frequently occupied by men-of-war and frigates at anchor. Sometimes a fleet of ſhips is ſtationed here. It is ſaid that 1000 ſail of veſſels may anchor at one time with ſecurity. The depth of water, at low tide, is 10, 11, 13, 14, 15, and 16 fathoms. This place is memorable for the ſhipwreck of the Royal George, of 100 guns, in Auguſt 1782. At that time the veſſel was occupied by more than 400 men and 200 women, and was hove on one ſide, for the purpoſe of repairing her keel. Not anticipating danger, the ſailors had neglected to laſh down her lower deck ports, and a ſudden ſquall coming on, ſhe was thrown with her broad-ſide on the water. The hole was filled in a few minutes, and every thing was carried to the bottom. Admiral Kempenfelt, with all the crew and viſitors, periſhed; for there was no time for boats to afford aſſiſtance. Many attempts have been made to raiſe this veſſel, but without ſucceſs; although many articles have been obtained from the cabins, &c. Some of the maſts continued to be ſeen above water for many years after the accident.

SPITHEAD *Creek*, a river of the weſtern territory of America, which runs into the Ohio, N. lat. 39° 56′. W. long. 80° 46′.

SPITTER, among *Sportſmen*, a red male deer near two years old, whoſe horns begin to grow up ſharp and ſpitwiſe.

It is otherwiſe called a *brocket* and *pricket*.

SPITTLE. See SALIVA and SPUTUM.

SPITTLE, a corruption of the word *hoſpital*.

SPITTLE, in *Agriculture*, the name of a ſpaddle or ſmall ſort of ſpade. See SPADE.

SPITTLING, a term applied to an operation performed in the cultivation of teaſle crops, in which the workman, with a tool of the ſpittle, ſhoe, or ſmall ſpade kind, turns over the ſurface-mould between every plant in a careful manner, in the firſt ſummer ſeaſon after planting, when the plants have acquired ſome degree of growth. By this means they are kept perfectly clean from weeds, and their growth promoted as much as poſſible.

The work commonly coſts about a guinea and a half the acre and drink, in moſt diſtricts where this ſort of cultivation is carried on. See TEASLE.

SPITZ, in *Geography*, a town of Auſtria, on the Danube; 10 miles above Krems.—Alſo, a town of Bohemia, in the circle of Leitmeritz; 9 miles N.E. of Kamnitz.

SPITZBERG, a conſiderable mountain of Sileſia, in the principality of Liegnitz.

SPITZBERGEN, or SPITSBERGEN. See *Eaſt* GREENLAND.

SPITZEBACH, a river of Germany, which runs into the Eltzach, near Ober Winden.

SPIZA, in *Ornithology*, a name by which the ancient naturaliſts called the chaffinch.

SPLA-BOARDS, in *Ship-Building*, boards or planks fixed to an obtuſe angle in the light-room, to throw the light into the magazine.

SPLACHNUM, in *Botany*, a name adopted by Montin and Linnæus from Dioſcorides, whoſe σπλαχνον is ſynonimous with his βρυον, and belongs to the Moſſes in general, or rather perhaps Lichens, which grow upon trees. This name becomes peculiarly appropriate, when we advert to its identity with σπλαγχνον, the Greek appellation of the principal *viſcera*, the heart, lungs, &c.; becauſe the eſſential character of the genus before us conſiſts in a peculiar fleſhy glandular organ, ſupporting the capſule; whence its Engliſh name, Gland-moſs.—Montin Diſſ. 7. Linn. Am. Acad. v. 2. 270. t. 3. Gen. 563. Schreb. 759. Hedw. Fund. v. 2. 88. t. 7. f. 33. Sp. Muſc. 51. Sm. Fl. Brit. 1169. Turn. Muſc. Hib. 15. Swartz Muſc. Suec. 22. Juſſ. 11. Lamarck Illuſtr. t. 874.—Claſs and order, *Cryptogamia Muſci*. Nat. Ord. *Muſci*.

Eſſ. Ch. Capſule cylindrical, placed on a fleſhy receptacle. Fringe ſimple, of ſixteen teeth, ſtanding in pairs.

This genus is one of the moſt remarkable of its tribe for ſize and beauty, as well as for ſingularity. Twelve ſpecies are defined in Hedwig's *Sp. Muſc.*; thirteen in the *Fl. Brit.* ſix of the latter not being known to Hedwig. Linnæus, in the original account of the genus, deſcribes but two, which are far the moſt extraordinary, natives of the moſt northern part of Europe, and not found in Britain. We ſhall deſcribe theſe, with a few of the others beſt worth notice.

S. *mnioides*. Green Tapering Gland-moſs. Linn. Fil. Meth. Muſc. 26. Hedw. Sp. Muſc. 51. Crypt. v. 2. 35. t. 11. Fl. Brit. n. 1. Engl. Bot. t. 1589.—Receptacle inverſely conical, green. Leaves elliptic-lanceolate, bearded, entire.—Native of moiſt alpine ſituations in Scotland, Wales, and other parts of Europe, generally, in Wales, growing on the dung of foxes and badgers, according to Mr. Griffith's remarks. This is one of the ſmaller ſpecies, reſembling ſome common *Bryum*; its leafy *ſtems* about an inch high; its *fruit-ſtalks* rather more. The *capſule* is cylindrical, brown, with a blunt lid. Its ſhort green *receptacle* at the baſe might almoſt be overlooked, as a ſwelling of the ſtalk.

S. *ſphæricum*. Green Globular Gland-moſs. Linn. Fil. Meth. Muſc. 33. t. 1. f. 1. Hedw. Sp. Muſc. 55. Crypt. v. 2. 46. t. 16. Fl. Brit. n. 8. Engl. Bot. t. 785.—Receptacle globular, green. Leaves ovato-lanceolate, pointed, entire. Fruit-ſtalk capillary.—Native of alpine ſituations in Lapland, Germany, Carniola, Scotland, &c. uſually on cow-dung. Dr. F. Buchanan firſt met with it at Leney near Stirling, in 1782. This forms green tufts, each plant being ſimple, apparently annual, about half an inch high in the leafy *ſtem*, which terminates in a ſtarry *bloſſom*. Some of theſe bloſſoms are moſt perfectly male, others female. The latter produce each an elegant ſlender wavy tawny *fruit-ſtalk*, from one and a half to three or four inches high, bearing a green, nearly globoſe, ſmooth *receptacle*, much larger and thicker than the little brown cylindrical *capſule*, bordered with eight pair of ſpreading brown teeth.

S. *gracile*, Dickſ. Crypt. faſc. 4. 3. t. 10. f. 5. Fl. Brit. n. 9. Engl. Bot. t. 1921, is ſuppoſed by Mr. Turner to be a variety of the laſt, rather ſmaller, with ſerrated points to the *leaves*, and a brown *receptacle*.

S. *ampullaceum*. Purple Gland-moſs. Linn. Sp. Pl. 1572. Hedw. Sp. Muſc. 55. Crypt. v. 2. 41. t. 14. Fl. Brit. n. 10. Engl. Bot. t. 144. Fl. Dan. t. 822. (S. n. 3; Linn. Am. Acad. v. 2. 280. Bryum ampullaceum, foliis thymi pellucidis, collo ſtrictiore; Dill. Muſc. 343. t. 44. f. 3.)—Receptacle inverſely conical, obtuſe, greeniſh-purple, thrice as thick as the capſule. Leaves lanceolate, acute, ſerrated.—One of the moſt common ſpecies, at leaſt in England, growing chiefly on rotten cow-dung on moiſt turfy heaths in the ſpring, ripening fruit in ſummer. It ſeems no leſs frequent in other parts of Europe. This is larger than *S. ſphæricum*, annual like that, but diſtinguiſhed by the narrower ſerrated *leaves*, ſtouter *ſtalks*, and eſpecially the large purple pear-ſhaped *receptacles*, each crowned with a little ſlender tawny *capſule*.

S. *Turnerianum*, Dickſ. Crypt. faſc. 4. 3. t. 10. f. 11. Fl. Brit. n. 11. Engl. Bot. t. 1116, is, we fear, but a ſmall, or ſtarved, variety of the laſt.

S. *vaſculoſum*. Crimſon Globular Gland-moſs. Linn. Sp. Pl. 1572. Hedw. Sp. Muſc. 53. Crypt. v. 2. 44. t. 15.—Receptacle blood-red, nearly globular. Leaves ſpatulate, bluntiſh, entire.—Native of turfy bogs near Upſal, and in other parts of Sweden. About the height of the laſt, but diſtinguiſhed by its blunt entire *leaves*, and the globular form, greater ſize, and deep rich hue of its *receptacle*. This fine ſpecies has alſo been found in Germany, but not in Britain.

S. *rubrum*. Red Umbrella Gland-moſs. Linn. Sp. Pl. 1572. Hedw. Sp. Muſc. 56. Crypt. v. 2. 51. t. 18. (S. n. 1; Montin Diſſ. 8. t. 1. f. 2. Muſcus norwegicus, umbraculo ruberrimo inſignitus; Petiv. Muſ. 11. t. 1. f. 70. Dill. Muſc. 547. t. 83. f. 9.)—Receptacle orbicular, convex, red. Leaves ovate, partly toothed.—Native of Norway, Finland, Ruſſia, and moſt parts of Siberia. The *ſtem*, like moſt of the reſt, is ſimple, leafy, about an inch high. Upper and floral *leaves* ſerrated. *Fruit-ſtalk* about ſix inches long, erect, red, bearing a ſmall cylindrical *capſule*, which is ſubtended by a moſt beautiful, large, and conſpicuous *receptacle*, like an inverted cup, half an inch wide, of a rich crimſon, finely reticulated, and certainly one of the moſt curious productions in this whole natural order.

S. *luteum*. Yellow Umbrella Gland-moſs. Linn. Sp. Pl. 1572. Hedw. Sp. Muſc. 56. Crypt. v. 2. 48. t. 17. (S. n. 2; Montin Diſſ. 9. t. 1. f. 1.)—Receptacle orbicular, flattiſh, deflexed, yellow. Leaves obovate, entire.—Native of boggy woods in Lapland and Weſtbothland. This vies with the laſt in magnitude and ſingularity, but the *receptacle* is pale yellow, and though deflexed, ſcarcely convex. By Hedwig's figures, as well as the Linnæan ſpecimens, this part ſeems to be ſmall and green till the *capſule* is fully formed, after which it expands and aſſumes its proper colour.

SPLAIT-Shoulder. See Shoulder.

SPLANCHNICA, a name given to medicines appropriated to diſeaſes of the bowels.

SPLANCHNOLOGY, formed from σπλαγχνον, *inteſtine*, and λογος, *diſcourſe*, in *Anatomy*, a diſcourſe on, or explication of, the viſcera.

Sarcology is divided into three parts, *viz*. ſplanchnology, myology, and angeiology; of theſe, ſplanchnology is that which treats of the internal parts, and particularly of the viſcera.

SPLEEN, in *Anatomy* and *Phyſiology*, (σπλην, *lien, la rate*,) a body about the ſize of a ſmall fiſt, of a texture rather reſembling that of glands, ſituated in the left hypochondriac region of the abdomen, between the great end of the ſtomach, and that portion of the diaphragm which lines the concavity of the tenth and eleventh ribs.

The organ is uſually ſingle; but occaſionally one, two, or more ſmall ſecondary ſpleens (lienes ſuccenturiati), of a round or oval figure, about the ſize of hazel-nuts, of a texture exactly ſimilar to the principal one, are found near its anterior end, in the great omentum, connected by the latter and by their blood-veſſels to the principal ſpleen.

It has been aſſerted that the ſpleen has been in ſome caſes entirely deficient. It may have been greatly diminiſhed by diſeaſe, or conſumed by ſuppuration; but we have no ſufficient teſtimony of its entire abſence as a defect of original formation.

Every thing belonging to the ſpleen is irregular, and its figure is remarkably ſo. Uſually the outline deſcribed by its circumference is elliptical: it repreſents, indeed, on the whole, the ſection of an ellipſoid carried through the axis. Its largeſt ſurface is convex, like the ſuperficies of an egg; the margin oval, with two ends, and a longer and ſhorter axis. The convex ſurface of the organ, then, is the moſt extenſive, riſing in the middle, and ſloping towards a comparatively thin edge: this is rather broader towards the back part, and grows narrower, terminating in an obtuſe point in front. The oppoſite aſpect is concave, and divided into two ſurfaces by a ſlight notch running along its long axis, at which the blood-veſſels enter, and to which the omentum is affixed. Both ends of the ſpleen are obtuſe: the poſterior or ſuperior is thicker, the inferior or anterior thinner. Sometimes the ſpleen is more rounded, or more triangular. Often the edge is notched in one or more places, and more or leſs deeply.

The ſituation of the ſpleen varies, as well as its figure. We may, however, ſtate generally, that in a healthy ſubject of the ordinary formation, it will be found in the upper and back part of the left ſide of the abdomen, covered by the falſe ribs, lying between the back of the great end of the ſtomach and the diaphragm in ſuch a way, that it is not viſible on opening the abdominal cavity until the ſtomach is drawn aſide. Its convexity correſponds to the concavity of the diaphragm, and of the tenth and eleventh ribs; its concavity to the great end of the ſtomach: one end is turned backwards; the other forwards.

In this ſituation it is cloſely tied to the ſtomach by its blood-veſſels, which ſend branches to that organ; and by the great omentum, which is attached to its notch, and to the neighbouring portion of the ſtomach. There are, beſides, certain folds of peritoneum, connecting it to the ſurrounding parts. One of theſe, ligamentum verticale, or ſuſpenſorium lienis, or phrenico-ſplenicum, paſſes from the lower part of the diaphragm to the upper end of the ſpleen. Another, ligamentum meſocolicum, or gaſtro-ſplenicum, paſſes from the meſocolon, ſtomach, and œſophagus, to the poſterior part of the notch. A fold of peritoneum may alſo be ſeen going from the ſpleen to the left renal capſule and kidney.

The changes of place in the ſtomach are attended with correſponding alterations of the ſpleen. When the former is full, the ſpleen is ſituated nearly tranſverſely, with one end turned backwards, and the other forwards, with its concavity touching the colon in front, and the renal capſule behind. As the ſtomach becomes empty, the poſition of the ſpleen is more perpendicular; with its ends upwards and downwards. The motions of the diaphragm are neceſſarily accompanied with change of poſition in the ſpleen. When that muſcle deſcends, it puſhes the ſtomach and ſpleen downwards and forwards, thruſting them from under the ribs; they are brought back again to their former place by the re-action of the abdominal muſcles.

When it is enlarged, it paſſes out of the hypochondrium, and can be felt in the umbilical region, or even the hypogaſtric: it has deſcended as low as the groin or bladder. In caſes of tranſpoſed viſcera, it has partaken the inverſion with the other thoracic and abdominal organs.

The ſize of the ſpleen, like other circumſtances belonging to this organ, is ſubject to much variety. Soemmerring ſtates its weight at from ſix to fifteen ounces; and its ſpecific gravity to that of water, as 1060 to 1000. It has been aſſerted, that the kind and the circumſtances of death influence the ſize of the ſpleen; and we may readily believe that a part of ſpongy texture, containing ſo much blood, will be ſmaller in an individual who has periſhed from hæmorrhage than in one who has died of aſphyxia. All phyſiologiſts have repreſented that the ſize of the ſpleen is influenced by the ſtate of the ſtomach, which they conceive to act on it in two ways. They ſuppoſe that the full ſtomach preſſes the ſpleen againſt the ribs, and thus mechanically forces out the contents of its cells, which are expanded again as ſoon as this preſſure is remitted. It has been alſo imagined, that when the ſtomach is full of aliment, blood paſſes in larger quantity into its veſſels, which admit it more eaſily; while, in the empty ſtomach, the veſſels fall into folds, and do not receive ſo much blood. In the former caſe, the blood which goes to the ſtomachic arteries is partly drawn away from the ſplenic veſſels, which alſo admit it leſs readily, becauſe the ſpleen is at the ſame time compreſſed: in the latter, theſe circumſtances are juſt reverſed. Theſe obſervations ſeem purely hypothetical; and they preſent a mechanical ſolution of vital proceſſes, which are certainly governed by other principles. Not a ſingle fact is adduced as a foundation of this fanciful ſuperſtructure. It ſeems, on the contrary, that there are facts ſufficient to overturn it. "Numerous comparative experiments," ſays Bichat, "made at different points of time in the digeſtive proceſs, during the plenitude and emptineſs of the ſtomach, on animals of ſimilar ſize, and under ſimilar circumſtances, have ſhewn, indeed, ſenſible variations in the volume of the ſpleen, but not that invariable coincidence, which has been aſſerted, between the contraction of the ſtomach and the increaſe of the ſpleen, and *vice verſâ*. The oppoſite relation was often noticed; ſo that we could only conclude, that the differences of volume were independent of the ſucceſſion of the digeſtive phenomena, and conſtituted permanent peculiarities of individual organization. The kidney, the liver, &c. do not exhibit an uniform ſize in all ſubjects; but we do not trouble ourſelves by endeavouring to find cauſes for ſuch variations.

"Laſtly, admitting that the volume of the ſpleen varies during life, whether theſe variations coincide or not with determined ſtates of the digeſtive organs, it is repugnant to the ſpirit in which modern phyſiology contemplates the phenomena of life, to aſſign the laxity of the ſpleen, when the ſtomach is empty, as a cauſe for the derivation of blood from the veſſels of the latter organ, or its mechanical compreſſion by the diſtended ſtomach, as a means of explaining the more rapid paſſage of the blood into the ſyſtem of the vena portarum." Anatomie Deſcriptive, t. v. p. 58.

We cannot doubt, that, independently of diſeaſe, or of ſuch natural cauſes as may produce changes in the ſtate of the ſpleen, the volume of this organ is different in different individuals. Animals of the ſame ſpecies and age, and under circumſtances in all reſpects ſimilar, exhibit ſuch differences. We frequently, too, find the ſpleen after death, in the human ſubject, conſiderably larger or ſmaller than what may be regarded as the ſtandard ſize, though alike in all other points; ſo that the kind of death, or other accidental circumſtance, will not explain the difference.

The colour of the ſpleen is red or livid, or of ſome tint between theſe. The convex ſurface is often red, while the edge and concavity are livid. The former colour is more prevalent in young, the latter in old ſubjects. When the organ is cut, its internal colour ſeems to depend on the large quantity of blood it contains; and nearly reſembles that of a coagulum, with divided blood-veſſels interſperſed through it.

It is ſpongy, ſoft, and delicate in its texture, ſo that it can be broken down by moderate preſſure with the fingers.

The ſpleen is ſurrounded externally by a ſmooth, thin, and cloſely-adhering ſerous membrane, derived from the peritoneum. This coat is ſo intimately united to the next, that they cannot be ſeparated. The proper membrane immediately incloſes the ſpleen. Although this and the former are inſeparably united, we cannot doubt that ſuch a proper membrane exiſts, becauſe the covering is much thicker than the peritoneum in any ſituation. Juſt at the notch, the peritoneum may be ſeparated for a ſhort diſtance from the proper membrane. From the internal ſurface of this covering, numerous fine filaments are continued into the ſubſtance of the ſpleen, where they form part of the peculiar tiſſue of the organ. The proper membrane is ſo thin, that its nature is not eaſily aſcertained: it ſeems, however, to belong to the fibrous claſs, as it is corrugated by boiling, and eaſily receives depoſitions of gelatine, or phoſphate of lime. Thickenings of the ſplenic coats from this cauſe are very common. This membrane is ſofter than thoſe of the fibrous kind uſually are; and it is elaſtic, ſo as to accommodate itſelf to the varying bulk of the organ.

The ſpleen is remarkable from the ſize of its artery, which is larger in proportion to the organ than in any other inſtance, although no ſecretion takes place. There are great varieties in the number of ſecondary branches, by which it penetrates the notch of the ſpleen. The hepatic artery is rather larger than the ſplenic in young ſubjects; but ſmaller in the adult; yet the liver in the latter is at leaſt five times larger than the ſpleen. The branches of the ſplenic artery are ſaid to be very large in compariſon with the trunk; and the coats of the artery are remarkably ſtrong. Its reſiſtance, compared to that of the aorta, near the emulgents, was as 1312 to 1000. The ſpleen has a large ſingle vein, which conſtitutes one of the principal trunks of the vena portarum. In a child of three months, according to Haller, the artery meaſured $\frac{12}{100}$dth of an inch, the vein $\frac{15}{100}$dth: in a child of eighteen months, the numbers were 13 and 19; at three years, 14 and 26. According to ſir Everard Home, "the trunk of the ſplenic vein, compared with that of the artery, when both are filled with wax, is found to be in the proportion of five to one in its ſize. This was aſcertained both by an accurate meaſurement of their diameters, and by weighing half an inch in length of each in a very nice balance: the diſproportion between them is greater than between correſponding veins and arteries in other parts of the body." (Phil. Tranſ. 1807. pt. ii. p. 49.) It has no valves. Injected fluids of all kinds paſs with the greateſt facility from the artery into the vein. There are numerous ſuperficial abſorbents, belonging principally to the peritoneum: of deep-ſeated abſorbents, there is little known. The abſorbents are eaſily demonſtrated in the calf. If air is impelled under the membrane of the ſpleen, numerous knotted lymphatic trunks appear, ariſing from the whole ſurface of the viſcus, and paſſing with the great blood-veſſels towards the receptaculum chyli. Many obſervers have noticed and deſcribed them in animals; but they are not ſo conſpicuous in man. The nerves are ſmall; they come from the cœliac plexus, and form a ſlender ſplenic plexus, ſurrounding the artery, and entering the ſpleen with its branches. If the organ, in its natural ſtate, poſſeſſes any ſenſibility at all, it is very inconſiderable. For further particulars on theſe points, ſee Artery, Vein, Nerve, and Absorbent.

The ſubſtance of the healthy ſpleen readily yields to any force, and is eaſily broken down. It appears, when divided, ſoft and ſpongy. Its colour is deeper than that of the ſurface. It ſeems thoroughly penetrated with blood, which is not coagulated, which may be ſqueezed out, but does not flow very readily. In ſome ſubjects, more particularly young ones, there is a granular appearance, ariſing from numerous ſmall bodies, called acini: theſe are rendered more viſible by breaking the ſpleen, and obſerving the broken ſurface. If the divided ſurface be ſcraped with a knife, blood is expreſſed, and ſome of the parenchymatous ſubſtance is uſually detached. If we ſubject it to frequent waſhings, the blood is diſcharged from it, and the organ is reduced to a looſe ſpongy tiſſue of whitiſh fibres and laminæ; many of which adhere to the internal ſurface of the fibrous membrane. If the blood is carefully preſſed out from the veſſels, and they are then waſhed out by repeated injections of water, the ſpleen, carefully inflated and dried, exhibits a mere cellular and ſpongy maſs.

This parenchyma of the ſpleen conſiſts of the blood-veſſels, ramified in the uſual way, and terminating in a capillary ſyſtem, and of certain cells, which are eaſily injected from the ſplenic vein with coarſe injection. The ramifications of the veins, and theſe cells, are of very delicate ſtructure, ſo that they eaſily give way under injection.

The cells of the ſpleen were noticed by Malpighi, who deſcribes in the organ a number of ſmall glands, hollow, and ſurrounded by arterial zones, into which he had never been able to trace any venous branches. Cuvier deſcribes ſmall corpuſcles, whoſe uſe is unknown. Sir Everard Home ſays, in his obſervations on the ſtructure and uſes of the ſpleen, "I have examined it after death, under the ordinary circumſtances, and have found the appearances deſcribed by Cuvier. I have alſo examined it frequently immediately after the ſtomach had received unuſual quantities of liquids, and in that ſtate have found invariably that the corpuſcles of Cuvier, which were the glands of Malpighi, are diſtinct cells, containing a fluid, which eſcapes when the cells are punctured, and renders their membranous coat viſible; ſo that it would appear that the diſtention of theſe cells is connected with the ſtate of the ſtomach, and therefore only takes place occaſionally; and that the elaſtic capſule, by which the ſpleen is ſurrounded, adapts the organ to theſe changes in its volume." Sir Everard ſtates farther, that "in the ſpleen of the bullock, horſe, and hog, the cells, when the arteries and veins are injected with coloured ſize, are ſeen to have numerous arterial branches ramifying in their coats, but no venal ones, which confirms the ſtatement of Malpighi: and when the cells are empty and contracted, and the blood-veſſels filled to a great degree of minuteneſs, the appearance of cells is entirely loſt, as ſtated by Cuvier. When the cells were in a diſtended ſtate, their cavities, in a great many inſtances, were very diſtinct, having been laid open in making a ſection of the ſpleen. The intermediate parts of the ſpleen are but ſparingly ſupplied with arterial branches; and the ſmaller ones (arteries?) do not appear to have any particular diſtribution. When the veins only are injected, their branches appear more numerous, and larger than thoſe of the arteries, making the whole ſubſtance of the ſpleen of a red colour. They appear to ariſe from the outſide of the cells, going off at right angles to their circumference, like radii. Where the injection has not been very minute, they are ſeen to ariſe at not many points of the capſule; but where the injection has got into ſmaller branches, their number is ſo much increaſed, that they appear to form plexuſes round the cells." Phil. Tranſ. 1808, p. 47—49.

In a ſecond paper on the ſame ſubject, ſir Everard informs us, "that the ſpleen is met with in two very different ſtates, one of which may be termed the diſtended, the other the contracted, and that in the one its ſize is double what it is in the other. In the diſtended ſtate there is a diſtinct appearance of cells containing a limpid fluid, diſtinguiſhable by the naked eye: in the contracted, theſe only become diſtinct when ſeen through a magnifying-glaſs. The diſtended ſtate takes place when the ſtomach has received unuſual quantities of liquids before the animal's death; and the contracted ſtate, when the animal has been kept ſeveral days without any drink, before the ſpleen is examined." Ibid. p. 140.

It is obſerved by Haller, that in the calf, and moſt other herbivorous quadrupeds, the ſtructure of the ſpleen is more obvious, and eaſily exhibited, than in the human ſubject. "In theſe animals, very ſtrong and evident fibres and laminæ ariſe from the external covering of the ſpleen, penetrate into the interior of the organ, are attached to the coats of the blood-veſſels, and laſtly, having decreaſed in ſize, end in all directions in the pulpy ſtructure of the ſpleen. In this way they compoſe a cellular tiſſue much more looſe than in man. If water be thrown into the vein, the organ then preſſed, and theſe proceedings repeated, until the fluid comes out clear, the whole may be diſtended, by inflation of the vein, into an appearance very much like that of the lungs. From this texture, there is a very free paſſage into the vein, which ſeems to open by very ſhort branches, as it were foramina, into the cellular tiſſues. The fibres are neither muſcular nor vaſcular, but cellular; on account of their ſtrength in the larger animals, ſome have called them ligamentous." Elem. Phyſiolog. lib. xxi. ſect. 1. § 15.

Heretofore great diſputes exiſted about the ſmall bodies called acini, which are obſerved in the ſubſtance of the ſpleen. Malpighi, who firſt noticed them, deemed them ſmall hollow glands. Ruyſch inſiſted that they were merely the minute veſſels aſſuming a peculiar arrangement; and that this ſtructure could be demonſtrated by ſucceſsful injections. The latter opinion has been gradually adopted by the beſt anatomiſts; among whom we may enumerate Albinus, Haller, and Soemmerring. "Qui nonnunquam occurrunt, acini vel glomeruli, microſcopii ope accuratiſſime explorati, nihil aliud ſunt niſi vaſorum faſciculi, vel teretes penicilli, aut cirri vaſculoſi." De Corp. Hum. Fabric. t. vi. p. 157.

The reſemblance of the ſpleen to glands in its ſtructure, has led to a very careful ſearch after an excretory duct; but nothing of this kind has ever been detected; although ſuch diſcoveries have heretofore been publiſhed. We know of no connection between the ſpleen and any other organ, except by means of blood-veſſels or nerves.

In a paper, containing experiments on the paſſage of fluids from the ſtomach into the general circulation, &c. publiſhed in the Phil. Tranſ. 1812, p. 51, ſir Everard Home advances the opinion, that a ſecretion takes place into the cells of the ſpleen, that the fluids thus ſecreted are conveyed by the abſorbents into the thoracic duct; and, conſequently, that thoſe veſſels are excretory ducts of the ſpleen. With deference to this ingenious and indefatigable inquirer, we may ſuggeſt, that the fact of the ſpleen performing any ſecretion is not yet proved; conſequently, that we need not employ ourſelves in diſcovering the means of conveying away ſuch ſecretion.

The blood of the ſpleen ſeems to be diſtinguiſhed by ſome peculiarities. It is never ſeen coagulated: Haller ſays that he never ſaw it in that ſtate; but according to Soemmerring, a true clot (polypus) has been obſerved in the ſplenic vein. (Elem. Phyſiol. t. vi. p. 404. De Corp. Hum. Fab. t. vi. p. 156.) It is ſaid to be darker coloured than other venous blood; but expoſure to oxygen gives it the ſcarlet tint.

Haller ſays alſo that it contains more water, the proportion of this element in it, compared to that in other blood, being as $\frac{34}{37}$ to $\frac{26}{39}$. The thick part ſubſiding to the bottom of the veſſel was leſs; as 3 to 6. Sir Everard Home confirms the fact of the greater quantity of ſerum in ſplenic blood. (Phil. Tranſ. 1808, p. 138.) Neither, according to the repreſentation of Haller, are theſe the only diſtinguiſhing characters of ſplenic blood. It has been found, he ſays, to contain more volatile ſalt, and leſs empyreumatic oil. The experiments on which the above obſervations are grounded afforded ſimilar reſults on repeated trials, and in various animals.

The ſpleen is very ſmall in the fœtus, and appears remarkably ſo, if compared to the kidnies or liver. It rather increaſes towards the end of pregnancy. No remarkable changes occur in it after birth: in old perſons it is often diminiſhed; and its external coat is thicker.

A ſpleen, or at leaſt a body ſo conſidered, and called by that name, exiſts in all the orders of the vertebral diviſion of animals; but, if we may judge from the ſize, its importance ſeems to diminiſh ſucceſſively from mammalia to birds, thence to reptiles, and from them to fiſhes. Mammalia reſemble man in having the ſpleen placed cloſe to the left end of the ſtomach; but they exhibit conſiderable varieties in the ſize, figure, colour, and texture of the organ. It is proportionally large in man, being twice as large as in the ox for example. In birds, reptiles, and fiſhes, the ſpleen is not only ſmaller, but firmer and more rounded; not ſo conſtantly placed near the ſtomach, but in the midſt of the meſentery for example. The relations and ſources of its blood-veſſels are alſo different. Inſtead of a large peculiar branch, it has ſmall branches from a ſtomachic artery, or from the meſenteric.

The uſe of the ſpleen ſtill remains a problem, towards the elucidation of which the inveſtigations of ſo many anatomiſts and phyſiologiſts have hitherto afforded very imperfect data. In beginning his obſervations on this ſubject, Haller very ſenſibly admoniſhes his reader that "he is plunging into the region of mere conjecture, darker than in the caſe of any other viſcus." We might have hoped to derive ſome light from the diſeaſes under which it frequently ſuffers, and from the experiments, in which it has been removed in animals. The inferences, however, to which we arrive in this way, are only of the negative kind; they enable us to deſtroy or refute, but not to build up or eſtabliſh. The ſpleen may be found conſiderably altered in texture, where the individual has enjoyed good health before death, or has died of other complaints. It is often enormouſly enlarged, without materially affecting the health; and, on the other hand, where ill effects are produced, they have no peculiar character, affording illuſtration of the uſe of the organ.

The experiment of removing the ſpleen ſeems to have been performed in very ancient times. Pliny ſays, that animals will live after this part has been torn out (lib. xi. c. 30.); and the ſame fact is noticed in the Talmud (Ginzburger, Medic. Talmud. p. 11.) Haller cites various inſtances, in which the ſpleen has been loſt in the human ſubject; particularly Leon. Fioravanti, teſoro della vita umana, l. ii. c. 8. Phil. Tranſ. N° 451. The removal of it from the dog is an experiment repeated over and over again. (See Haller, t. vi. p. 421.) We find that animals, and even human ſubjects, have lived without a ſpleen, and enjoyed tolerable health. Sometimes the experiment has been fatal, but not from the loſs or interruption of any function, that could be aſcribed to the ſpleen. We find that dogs have been lively, fat, and even plethoric; that they have had good appetites; that bitches have produced young. Some thought they were more ſalacious; others, that they made water more frequently. In ſome caſes appearances were noticed, that might be referred to imperfection in the digeſtive proceſs, as borborygmi. The liver is ſaid to have ſuffered, in a few inſtances: in moſt, however, there ſeems to have been good bile made; and generally no particular ill effect was experienced.

The inference, then, to be collected from theſe ſources is, that the function of the ſpleen is of ſo little importance, that the alteration of its texture by diſeaſe is not marked by any unequivocal ſymptom, and even that its entire removal is hardly followed by any ſenſible effect.

It has been a generally received, and long prevalent notion, that the office of the ſpleen is related to that of the liver; that the blood, either by its retarded motion through the ſerpentine ſplenic veſſels, its ſtagnation in the ſplenic cells, or other changes wrought in it by the actions of the ſpleen, acquires peculiar properties, rendering it fit for the ſecretion of bile in the liver. It is ſuppoſed that the ſplenic blood is loaded with carbon, which the action of the liver ſeparates from it. We do not uſually meet with ſuch arrangements as theſe in the animal economy: indeed no inſtance could be adduced of the like nature;—one organ to carbonize the blood, that it may be decarbonized by another; or a part to produce changes in the blood, fitting it for the ſecretion which is to be performed by another. The tiſſue of each gland has the power of extracting its peculiar ſecretion from the common maſs. That the ſpleen produces changes in the properties of the blood is not yet clearly proved: ſtill leſs is it proved that ſuch changes, if produced, are in any way concerned with the biliary ſecretion. Further, bile is ſecreted where the ſpleen has been removed; and it was ſecreted, in the caſe recorded by Mr. Abernethy, where the vena portarum emptied its blood into the inferior vena cava. We obſerve no conſtant relation between the ſpleen and liver: the former is extremely ſmall in many birds, reptiles, and fiſhes, where the liver is large.

The cloſe neighbourhood of this organ to the ſtomach, and the connection of their blood-veſſels, have led to the conjecture that they are connected in function. It has been imagined, that when the ſtomach is empty, the ſpleen, like a ſponge, ſwells with blood, and affords a reſervoir for the quantity of that fluid, which the blood-veſſels of the ſtomach do not require in the inactive ſtate of the organ; while, on the contrary, when this bag is diſtended with food, and the proceſs of digeſtion demands a more copious afflux of fluids into the ſtomachic veſſels, the preſſure of its great extremity empties the ſplenic ſponge, and thus cauſes a greater flow in the other parts of the cœliac ſyſtem. This, again, is all imaginary: not a ſingle point of it founded in obſervation. It is quite inapplicable to the three lower claſſes of vertebral animals, where the poſition of the ſpleen in many inſtances, and its firmneſs in ſeveral, are quite incompatible with the explanation.

In two papers, publiſhed in the Philoſophical Tranſactions for 1808, on the ſtructure and uſe of the ſpleen, ſir Everard Home attempted to prove, that fluids are conveyed from the cardiac end of the ſtomach into the ſpleen, and thus arrive in the general circulation, without the intervention of the general abſorbing ſyſtem and thoracic duct. Having tied the pylorus, he injected coloured fluids into the ſtomach: they were partly abſorbed, and manifeſted their preſence in the circulating ſyſtem by changes produced in the urine. When rhubarb was uſed, the cut ſurface of the ſpleen produced a decided yellow tint on paper, and the ſerum of the ſplenic blood manifeſted the preſence of rhubarb, on the addition of potaſh; when no ſuch phenomena were

were exhibited by the cut ſurface of the liver, or in the ſerum of blood from the vena cava. There was a correſponding difference between the effects of potaſh on fluids, in which the ſubſtance of the liver and that of the ſpleen were broken up. The author abandons this notion in a ſubſequent communication to the ſame ſociety, on the paſſage of fluids from the ſtomach into the general circulation; having found that correſponding phenomena were exhibited, after the ſpleen had been removed. Phil. Tranſ. 1812.

Of numerous other dreams about this myſterious organ, ſuch as that it forms the red globules of the blood, that it is the ſeat of laughter, or of the ſentient ſoul, that it is deſigned to balance the liver, &c. &c. we can ſay no more than that thoſe who are intereſted in ſuch ſpeculations will find ample amuſement in Haller's Elem. Phyſiol. lib. xxi. ſect. 2; or in Soemmerring de Corp. Hum. Fabrica, t. vi. p. 158, et ſeq. One fact, mentioned by the latter author, may be ſtated, *viz.* that ſteel given for ſome time to animals has the effect of diminiſhing the ſize of the ſpleen.

Spleen, *Diſeaſes of the,* in *Medicine.* Much more has been written by the older writers reſpecting the diſeaſes of this organ, than by thoſe of the laſt half century. This may have ariſen partly from the greater accuracy of modern pathologiſts, but chiefly perhaps from the actual diminution of theſe maladies, in conſequence of the diminution of the prevalence of intermittent fevers, of which many of the chronic derangements of the ſpleen were the *ſequelæ,* or direct reſult. The *infarction* of the ſpleen, of which the older authors ſo often treat, was of this nature. The two principal modifications of diſeaſe, to which this viſcus is ſubject, are inflammation, and their indolent enlargement of its ſubſtance, formerly called infarction. We ſhall treat of theſe diſeaſes ſeparately; and then enumerate ſome of the other morbid conditions, with which the ſpleen has been occaſionally obſerved to be affected.

Spleen, *Inflammation of, ſplenitis* of the noſologiſts. This may occur, as in the other viſcera, in two forms; either attacking the inveſting membranes, or the ſubſtance of the gland. Under both forms, however, it is a rare diſeaſe, but eſpecially under the latter, the ſymptoms of which are apparently obſcure, and not ſatisfactorily underſtood.

The peritonæal coat of the ſpleen is, in fact, ſeldom inflamed, according to the teſtimony of that excellent anatomiſt, Dr. Baillie, unleſs when the peritonæum in the neighbourhood is alſo affected. The proper capſule of the ſpleen, he remarks, is ſo intimately connected with the peritonæum, which is reflected over it, that it muſt neceſſarily partake of any inflammation affecting that membrane. Accordingly the ſymptoms, attending this inflammation of the coats of the ſpleen, are not to be diſtinguiſhed from thoſe which characterize inflammation of that portion of the peritonæum which lies in the left hypochondrium (ſee Peritonitis); that is to ſay, there is pain in that region, more or leſs violent according to the degree of the inflammation, which is increaſed by preſſure, and is accompanied by a ſenſe of heat and tenſion in the part. There is alſo more or leſs of ſymptomatic fever, heat of ſkin, quickneſs and hardneſs of pulſe, thirſt, &c.; and, if the inflammation be conſiderable, ſome difficulty of breathing. The laſt ſymptom ariſes from the preſſure of the diaphragm, when deſcending, in the act of inſpiration, upon the inflamed parts. As the uſe of the ſpleen in health is unknown, we cannot, of courſe, look for any ſymptom characteriſtic of its diſordered function, as in the caſe of other large viſcera; but muſt infer that it is the ſeat of inflammation, from the ſituation of the pain, and from the abſence of diſturbance, in any conſiderable degree, in the functions of the neighbouring viſcera; as in that of the kidnies, exhibited in the urine; in that of the ſtomach, great inteſtine, &c.

It is probable, however, that the inveſting membrane of the ſpleen is liable to ſome degree of inflammation, which is not always noticed; for it has been remarked by the able pathologiſt juſt quoted, that it is not uncommon to find adheſions between the ſpleen and the neighbouring parts. Thoſe adheſions conſiſt of a white tranſparent membrane of more or leſs firmneſs, and generally connect the broad ſurface of the ſpleen more or leſs cloſely to the diaphragm. They often alſo connect the ſpleen to the great end of the ſtomach, and a part of the tranſverſe arch of the colon. See Baillie's Morbid Anatomy of ſome of the moſt important Parts of the Human Body, chap. xi.; and Morgagni de Sedibus et Cauſ. Morborum.

The inflammation or ſuppuration of the ſubſtance of the ſpleen is a very rare occurrence; but ſuch caſes have been occaſionally obſerved, and related by authors. (See Lieutaud, Hiſtor. Anatom.-Medica, tom. i.) This writer has even related inſtances of mortification of the ſubſtance of the ſpleen; but neither Morgagni nor Baillie have obſerved ſuch caſes. The ſymptoms which have been deſcribed, as belonging to inflammation of the ſubſtance of the ſpleen, are, a dull pain, with a ſenſe of fulneſs, in the left hypochondrium, the pain being increaſed on preſſure, and accompanied by the general diſturbance of the ſyſtem, called fever. The diſeaſe, however, is ſo rare, that ſufficient obſervations have ſcarcely been made to determine ſatisfactorily the diagnoſis of this malady. In two caſes, in which the inflammation of the ſpleen had advanced to ſuppuration, which were examined by Dr. Hunter, the patients were unable to define accurately the ſeat of their pain, which ſeemed to travel a good deal over the general cavity of the abdomen.

Although the diagnoſis be imperfectly eſtabliſhed, however, the ſame practice will be efficacious, which experience has found to be remedial in the inflammation of the peritonæal coat, or of the ſubſtance of other viſcera, and of the peritonæum lining the abdomen; that is, the early uſe of blood-letting, and purgatives, with bliſters and local bleeding, as circumſtances may require; and the ſteady adoption of the antiphlogiſtic regimen, as directed in the treatment of other viſceral inflammations. (See Peritonitis, Hepatitis, &c.) We ſhall, therefore, proceed to deſcribe the ſecond form of diſeaſe peculiar to the ſpleen.

Spleen, *Tumid.* This diſeaſe of the ſpleen conſiſts of an indolent enlargement of the ſubſtance of the viſcus, which, at the ſame time, becomes much harder than natural. It will occaſionally be enlarged to five or ſix times its natural ſize, and it then forms a tumour very capable of being diſtinguiſhed in the living body. When examined after death, the natural ſtructure ſeems to be preſerved, except that it is much more compact, the parts being much more cloſely applied together. When this tumour and induration are the conſequence of intermitting fever, the maſs is called an *ague-cake.* In general, this ſtate of the ſpleen is conſidered as ſcirrhous; but its ſtructure, as Dr. Baillie remarks, is not ſimilar to ſcirrhus in other parts of the body. It may, therefore, be doubted whether this is a proper ſcirrhous affection of the ſpleen, or whether it is not, in fact, ſomething eſſentially different.

The ſymptoms accompanying an enlarged and indurated ſtate of the ſpleen, in its early ſtages, are not very manifeſt or urgent; in fact, the exiſtence of the diſeaſe is commonly not ſuſpected, till it has made a conſiderable progreſs. It is uſually not accompanied by any pain or uneaſineſs; and will even bear a pretty ſtrong preſſure, without

out any painful ſenſation. But when the tumid ſpleen has attained a conſiderable ſize, it may be diſtinctly felt by the hand, and diſtinguiſhed by its ſituation and general ſhape. Its anterior edge may be traced under the margin of the ribs upon the left ſide, and it is ſometimes aſcertained by this examination to be notched. Under this ſtate of the diſeaſe the patient can only lie upon the left ſide; but he uſually complains of a ſenſe of fulneſs and weight, rather than of pain, dragging downwards towards the left ſide, and of ſome oppreſſion of the ſtomach after eating. The complexion is always of a dirty, ſallow, or leaden hue. The patient is alſo ſaid to be liable to hæmorrhages of the noſe. If the enlargement goes on, it reduces the body to great emaciation, and at length terminates in an incurable dropſy. Dr. Pemberton mentions a tumid ſpleen, which he ſaw, which weighed three pounds two ounces. See Baillie, loc. cit. Pemberton on Various Diſeaſes of the Abdom. Viſcera, chap. v.

The laſt-mentioned author conjectures, that the ſpleen may be thus affected with a *ſwelling* of its ſubſtance, merely from a larger quantity of blood being conveyed to it by the arteries, without theſe arteries taking on that action which is eſſential to inflammation. It is evident, indeed, that this enlarged and compact ſtate of the viſcus is ſomething entirely different from the ordinary reſults of inflammation, and is perhaps peculiar to the ſtructure of the ſpleen alone. It will not unfrequently ſubſide ſpontaneouſly, or with the aſſiſtance of medicines, to its natural ſize, and ſeems to be accelerated in that progreſs by the uſe of mercurial friction upon the abdomen, and by the adminiſtration of purgatives. The patient ſhould perſevere in the mercurial courſe, till the mouth is ſlightly affected, and then it ſhould be gradually laid aſide. Small doſes of calomel, in union with the extract of conium, anſwer the double intention of allaying the irritation of the ſtomach, and of promoting abſorption; and if there is a conſiderable degree of tenderneſs, which is ſometimes produced by an enlarged ſpleen about the articulations of the falſe ribs with the ſpine, it may be removed either by leeches or cupping. The diet of the patient ſhould conſiſt of milk, gruel, and a ſmall quantity of animal broth.

With reſpect to the prognoſis, Dr. Pemberton obſerves, the moſt favourable ſymptoms are, a diminution of the uneaſy ſenſations in the left ſide, and an improvement in the colour of the ſkin: the moſt unfavourable are, an increaſe of the ſwelling of the left ſide, and the lower part of the abdomen becoming enlarged: and if this part gives a ſenſation of fluctuation, the caſe is almoſt hopeleſs. Loc. cit.

Spleen, *Morbid Changes of the.* Among the other morbid conditions of the ſpleen, to which we have already alluded, may be mentioned, firſt, an extreme *ſoftneſs* of the organ, which is not uncommon in middle and more advanced life. In theſe caſes, the ſubſtance of the ſpleen ſeems to conſiſt of little elſe than a very ſoft browniſh-red mucus, intermixed with a ſpongy fibrous texture. This ſtate of the ſpleen is not marked by any peculiar feelings, ſo as to make the perſons conſcious of any diſeaſe, and is probably of very little conſequence in the general economy of the animal. The ſpleen, indeed, is ſaid to be occaſionally wanting, as a defect in the natural formation, and it has even been cut out, both from men and quadrupeds, without occaſioning them to ſuffer any inconvenience afterwards. Another diſeaſe of the ſpleen is the occurrence of *tubercles* in its ſubſtance, very ſimilar to the ſcrofulous tubercles of the lungs, which are placed at regular diſtances from each other, and do not run into maſſes, and ſeldom or never ſuppurate. *Hydatids*, of the ſame kind with thoſe found in the liver, are occaſionally formed in the ſpleen; but they are much more common in the former viſcus. *Calcareous concretions* have alſo been ſeen occaſionally in the ſpleen, but they are very rare. Sometimes the ſpleen has been ruptured, in conſequence of external preſſure upon that ſide of the body where it is ſituated. This accident can ſeldom take place, when the ſpleen is of the common ſize, becauſe it is well defended by the ribs; but it may readily happen, when the ſpleen is very large, ſo that a part of it paſſes below the margin of the ribs into the cavity of the flank. The only other morbid condition of any importance, which affects the ſpleen, is an occaſional converſion of its coats into a *cartilaginous* ſubſtance, which is almoſt excluſively obſerved in this viſcus. The cartilage is generally found in its convex ſurface, and rather reſembles the cartilages of the ears and noſe, than that which is found at the extremities of bones. Theſe varieties of diſeaſe are not to be diſtinguiſhed during life by any peculiar ſymptoms.

Spleen, in *Ichthyology.* The ſpleen in fiſhes is uſually ſituate near the ſtomach in the left ſide of the abdomen. Its figure is generally triangular, ſometimes oblong. Its colour is always more duſky and obſcure than that of the liver. See Fish.

Spleen *of Birds*, in *Ornithology.* See *Anatomy of* Birds.

Spleen-*Wort*, in *Botany*, &c. See Asplenium and Milt-*waſte.*

Spleen-*Wort, Rough.* See Lonchitis.

SPLENECTOMIA, the name given to the chirurgical operation of cutting out the ſpleen.

SPLENETIC, σπληνικος, a perſon affected with oppilations and obſtructions of the ſpleen.

In ſplenetic people, the ſpleen is ſwelled beyond the natural bulk; or it is hardened ſo, as to ſhew a ſchirrous tumour in it.

Splenetic people are diſtinguiſhed by a livid, lead-coloured complexion; and their character is, to be very prone to laughter; which is an expedient nature is ſuppoſed to make uſe of, to evacuate the too redundant humour the ſpleen is charged withal; whence it is, that the ancients made the ſpleen the organ of laughter; and hence that popular ſaying, of a perſon laughing heartily, that he *vents his ſpleen.*

Splenetic *Waters.* See Water.

SPLENIA, compreſſes reſembling the ſpleen in ſhape.

SPLENIC Vessel, a large artery and vein of the *ſpleen*; which ſee.

SPLENITIS. See Spleen, *Inflammation of.*

SPLENIUS, called alſo *maſtoideus poſterior*, in *Anatomy*, a flat, broad, oblong muſcle, ſituated obliquely between the back part of the ear, and the poſterior and lower part of the neck.

It is partly ſingle, and partly made up of two portions, one ſuperior, the other inferior. Theſe two portions are cloſely united backward, making only one plane, but they are divided above.

The two ſplenii repreſent a great Roman V, and the ſplenius, and ſterno-maſtoideus of the ſame ſide, form a figure like a Roman A, or the legs of a pair of compaſſes, the points of which are in an horizontal plane.

The two ſplenii ſerve to ſupport the head in an erect poſture, whether in ſtanding or ſitting; to moderate the flexion of the head forward, and to bring it back again to its natural poſture. They ſerve alternately to co-operate with either of the ſterno-maſtoidei for the rotation of the head. The complexi are aſſiſtants to the ſplenii, to keep the head ſtraight in ſitting or ſtanding, to hinder it from inclining forward, and to raiſe it when inclined. When they act together, they, as well as the ſplenii, may move the head backward, while the trunk is bent forward, or when we lie upon the belly; this latter motion is commonly called *extenſion*, the other *flexion*. See STERNO-CLEIDO-MASTOIDEUS.

SPLENIUS *Capitis*, a name given by Albinus to a muſcle, called by Winſlow, and others, the *maſtoideus ſuperior*, or upper portion of the ſplenius. Riolanus, and others, call it the *triangularis ſplenii*.

SPLENIUS *Colli*, a name given by Albinus to the muſcle, called by Winſlow, and others, *maſtoideus poſterior*, or the lower portion of the ſplenius; and by Cowper, the *muſculus inferior ſplenii*.

SPLENOCELE, a ſwelling of the hernial kind, produced by the ſpleen. Although ſuch is the meaning of this word, we believe the diſeaſe expreſſed by it is more imaginary than real. Its poſſibility may well be doubted.

SPLENT, or SPLINT, among *Farriers*, a callous, inſenſible excreſcence or griſtle, that ſometimes ſticks to a horſe's ſhank-bone, generally on the inſide below the knee. If there be one oppoſite to it on the outſide, it is called a *pegged* or *pinned* ſplent; becauſe it does as it were pierce the bone, and is extremely dangerous. Some call this a *double* ſplent, and others a *thorough* ſplent.

Some horſes are more ſubject to ſplents than others; but young horſes are moſt liable to theſe infirmities, which often wear off, and diſappear of themſelves. Team-horſes are very apt to have them. Few horſes put out ſplents after they are ſeven or eight years old, unleſs they meet with blows or accidents. A ſplent that ariſes in the middle of the ſhank-bone is no ways dangerous; but thoſe that ariſe on the back part of this bone, when they grow large and preſs againſt the back ſinew, always cauſe lameneſs or ſtiffneſs by rubbing againſt it; the others, except they are ſituated near the joints, ſeldom occaſion lameneſs.

It may be noticed, in reſpect to the cure of ſplents, that the beſt way is not to meddle with them, unleſs they are ſo large as to disfigure a horſe, or ſo ſituated as to endanger his going lame. Splents in their infancy, and on their firſt appearance, ſhould be well bathed with vinegar or old verjuice; which, by ſtrengthening the fibres, often puts a ſtop to their growth; for moſtly the membrane covering the bone, and not the bone itſelf, is here thickened; and in ſome conſtitutions, purging, and afterwards diuretic drinks, will be a great means to remove the humidity and moiſture about the limbs, which is what often gives riſe to ſuch excreſcences. Various are the remedies preſcribed for this diſorder: the uſual way is to rub the ſplent with a round ſtick, or the handle of a hammer, and then touch it with oil of origanum. Others lay on a pitch plaſter, with a little ſublimate, or arſenic, to deſtroy the ſubſtance: ſome uſe oil of vitriol, ſome tincture of cantharides; all which methods have at times, it is ſaid, ſucceeded; only they are apt to leave a ſcar, with the loſs of hair. Thoſe applications that are of a more cauſtic nature, often do more hurt than good, eſpecially when the ſplent is grown very hard, as they produce a running for ſeveral months, which often leaves an ugly ſcar. Mild bliſters, often repeated, ſhould be firſt tried as the moſt eligible method, and will generally ſucceed, even beyond expectation: but if they fail, and the ſplent be near the knee or joints, fire and bliſter, in the ſame manner as for the bone ſpavin.

Splents on the back part of the ſhank-bone are difficult to cure, by reaſon of the back ſinews covering them; the beſt way is to bore the ſplent in ſeveral places with an iron not very hot; and then to fire in the common way, not making the lines too deep, but very cloſe together.

SPLENTS, in *Surgery*, pieces of wood uſed in binding up broken limbs. See FRACTURE and SPLINTS.

The word is alſo ſometimes uſed for the pieces of a fractured bone.

SPLICE, *To*, in *Sea Language*, is to join the two ends of a rope together, or to unite the ends of a rope to any other part of it. There are ſeveral different methods of performing this operation, according to the ſervices on which it is to be employed. The *ſhort* ſplice is made by untwiſting the ends of two ropes, or the two ends of one rope, and having placed each of the ſtrands of one oppoſite to, and in the interval between two ſtrands of the other, to draw them cloſe together; and then interweave the ſtrands of the one into the alternate ſtrands of the other, by penetrating the latter with a fid or marline ſpike, parallel to the axis or length of the rope. This ſplice is uſed on the cables, ſlings, block-ſtrops, and in general all ropes which are not deſigned to run through blocks, or where the ſplice is not in danger of being looſened or ſeparated.

The *long* ſplice, being fixed in three places, occupies a greater extent of the rope; but by the diviſion of the joinings, the bulk is alſo divided into different parts of its length. Hence, it is much neater and ſmoother than the ſhort ſplice, and better adapted to run through the channel of a block, &c. for which uſe it is generally calculated.

The *eye-ſplice* being intended to make a ſort of eye or circle at the end of a rope, the ſtrands are untwiſted, and their extremities thruſt through the three ſtrands in that part of the ſaid rope on which the ſplice is to be formed, and thence paſſing over the ſurface of the ſecond ſtrand, they are again thruſt through the third, which completes the operation.

The *cut-ſplice* is conſtructed in the ſame manner as the eye-ſplice; being no other than the ends of two lines faſtened together, at a ſhort diſtance from each other, the extremities of either being interwoven into the bight of the other, ſo that the line becomes double in the extent of the ſplice. This is chiefly uſed in lead-lines, log-lines, and fiſhing-lines, where the ſhort ſplice would be liable to ſeparation, as being frequently looſened by the water. Falconer.

The *tapered* ſplice, moſtly uſed on cables, is made by unlaying a certain length of each cable, then placing them together, and interplacing the ſtrands, as in the ſhort ſplice, twice each way, and hauled tight each time; then inlay the ſtrands, or ends, ſucceſſively, and reduce them to a ſingle ſtrand, which is again thruſt through, and cut off. The ſplice is then ſerved over with ſpun-yarn, ſomething more than the whole length. *Drawing-ſplice*, uſed on cables, is made by unlaying about three fathoms of the ends; then place them together, and make a ſhort ſplice; then leave about one fathom, and from thence reduce each ſtrand to a long taper, by gradually cutting away as many yarns as neceſſary, and neatly point over the taper; then lay the ends up the cut-lines, and clap in a quarter-ſeizing at each end of the ſplice, an end-ſeizing at the beginning of the pointing, and a ſtop at the ends of the tails. This is the beſt ſplice for cables, as it may be readily taken aſunder. Another good method of making a *cable-ſplice* is to put the ends in twice each way; then to pick out the ſtrands, worm part of them round the cable, and taper away the reſt, which ſhould be marled cloſe down; then clap on a good throat and two end-ſeizings of ratline.

SPLICE, *To*, among *Gardeners*, is to graft the top of one tree into the ſtock of another, by cutting them ſloping, and faſtening them together.

SPLINTS, in *Ancient Armour*, a defence for the arms, which conſtituted part of the ſuit denominated an Almaine ryvatt.

Splints, are long pieces of thin wood, or paſteboard, uſed in *Surgery*, for affording ſupport and ſteadineſs to fractured bones.

SPLINTERS *of the Bone*, in *Fractures*. In caſes of fractures, the ſurgeon is frequently troubled with ſplinters of the bone in the way, which vellicate and prick the neighbouring parts, and render the proper execution of his office very difficult. If theſe ſplinters are looſe, and have no connection with the bone, they muſt be carefully lifted out of the wound; if they hang to the bone in ſome part by the perioſteum, that muſt be cut off with the ſciſſors; but if they adhere pretty firmly to the neighbouring parts, and do not hinder the reduction of the bone, it is beſt to replace the bone, and leave them either to looſen, and come out of themſelves by the ſuppuration of the parts, or to grow again, as they ſometimes will ſafely and firmly do, to the reſt of the bone. When they adhere pretty firmly to the principal parts of the bone, they ſhould never be extracted by force, but replaced with the greateſt exactneſs; for when this is properly performed, they will frequently unite to the reſt of the bone.

When the points of ſplinters of bones ſtick ſo far out, that they are a great hindrance to the reduction of the bone, you are diligently to conſider whether you can, by any means, contrive their reunion to the bone, which may be determined, by obſerving at what diſtance they are from the large bone, and what quantity of fleſh there is intervening: when they cannot be reduced, or reunited to the bone, they muſt be removed with a pair of ſtrong forceps, or, if they ſtick very firmly, with a fine ſaw. If the ſplinters are buried under the ſkin, and cannot be got at with hands, it is proper firſt to try if they can be reduced to their natural ſituation; and if they cannot, an inciſion muſt be made through the ſkin, that they may be taken out. See Fracture.

SPLIT, in *Botany*, a name given by ſome authors to the great *fumaria bulboſa*, or hollow root.

Split, at *Sea*. When a ſail is blown to pieces, the ſeamen ſay it is ſplit.

Split, when applied to a ſhip, denotes the ſtate of being ſtranded and bilged on a rock or ſhore.

Split *Rock*, in *Geography*, a rocky headland on the W. ſide of lake Champlain; 56 miles N. of Skeneſborough.

SPLITTING, in *Agriculture*, a term employed in the practice of paring land with the plough in ſome diſtricts. In it the plough always turns upon the left of the firſt furrow, and the coulter is held cloſe all the way to the lifted ſlice previouſly turned over, and which now covers a balk or rib of whole unmoved ground. The ſame ſort of work, in ſome of the eaſtern diſtricts of this country, is denominated wreſt-balking; but the practice has there a very different intention to that which induces it in the county of Devon and ſome others.

It is a term which is likewiſe uſed in common ploughing to ſignify the diviſion of the ridges, by making the furrow parts of the old ones the middle parts of the new ones. Thus, by beginning at the furrows, and laying the furrow ſlices of the different ridges towards each other, by continually turning in that direction, the furrows become the middles and the middles the furrows. It is uſed in oppoſition to *gathering*, which has the contrary effect.

It is uſed too in ſetting and taking up ſome ſorts of crops which are ſet in particular manners, as thoſe of the potatoe kind, when ſet in the ridge method, as by ſplitting the ridges with the plough or other tool, the ſets are uncovered, and perſons are enabled to pick and ſecure the potatoes, &c.

Splitting. To ſplit a thin piece of metal, as an old ſilver groat, place the metal on the heads of three pins ſtuck up triangularly, and let a heap of flour of brimſtone burn out upon it; then throwing it hard againſt the floor, the upper part will ſeparate from the lower. Boyle's Works, abr. vol. i. p. 134.

SPLUGEN, in *Geography*, a mountain in the county of Chiavenna; 8 miles N.W. of Chiavenna. Towards the ſummit of the mountain is an oval plain, about two miles long and one broad, encircled with craggy points: it produces no trees, but yields rich paſturage: near the ſummit are rude blocks of a whitiſh kind of marble. Above this oval plain is the ſource of the Lira, which falls into the lake of Chiavenna. On the other ſide of the higheſt ridge the torrents flow towards the Rhine. The paſſage over mount Splugen is principally uſed for the tranſport of merchandize to and from Coire; it is kept open even in winter, though not without great difficulty: in that ſeaſon the merchandize is chiefly tranſported on ſledges, of which forty or fifty paſs in a day.—Alſo, a town of the Griſons, ſituated upon the riſe of a hill, at the bottom of a rugged chain of Alps, and principal place of a juriſdiction, in the Rheinwald; 16 miles N.W. of Chiavenna. Two high roads meet at Splugen; one from Chiavenna, and the other leading over the Bernard into Bellinzone. From Splugen to Arder the road continues by the ſide of the Hynder Rhine, through a mountainous region, which preſents at every ſtep the moſt awful magnificence of ſcenery.

SPODDEN, a river of England, which runs into the Roch, at Rochdale, in Lancaſhire.

SPODIUM, in *Pharmacy*, a kind of abſorbent calx, or aſhes, eſteemed drying, and by ſome held to have the ſame virtues with coral.

The ſpodium of the ancient Greeks was a greyiſh kind of recrement, found in form of aſhes, on the hearths of furnaces in which braſs was made; and called by them σποδιον, which literally ſignifies *aſhes*.

Spodium is a metalline powder, nearly akin, both in origin and uſe, to tutia and pompholyx; only it is heavier than either.

The ſpodium of the Arabian phyſicians, as Avicenna and others, was made of the burnt roots of ruſhes and reeds. Some moderns alſo make a ſpodium of ivory burnt and calcined to a blackneſs. This is ſometimes counterfeited by burning bullocks' or dogs' bones; but theſe are of no value.

The anti-ſpodium, which the ancients ſubſtituted for their ſpodium, was made of myrtle-leaves, galls, and ſome other ingredients calcined.

SPODUMENE, in *Mineralogy*, *Triphane*, Haüy, a mineral which bears ſome reſemblance to adularia, but differs from it in the ſtructure, which is foliated, with a threefold cleavage. It divides into priſms with rhomboidal baſes, having alternate angles of eighty and one hundred degrees. It is tranſlucent and frangible, but ſomewhat harder than glaſs. The colour of ſpodumene is a greeniſh-white or grey, and ſometimes oil-green. The ſpecific gravity is from 3.192 to 3.218. It occurs, both maſſive and diſſeminated, at Uton, in Sudermanland, Sweden, at which place it has only been found at preſent. Before the blowpipe it ſeparates into ſmall gold-coloured laminæ, which melt by a continuation of the heat into a greeniſh-white glaſs.

The conſtituent parts of this mineral are given by Vauquelin as under.

Silex	-	56	to	64
Alumine	-	24	to	24.4
Lime	-	5	to	3
Potaſh	-	-		5
Oxyd of iron	-	5	to	2

SPOHREN, in *Geography*, a town of Saxony, in the circle of Leipſic; 2 miles S. of Zorbig.

SPOIL-BANK, a term expreſſing any heap of ſpare earth or ſtuff which remains, or is laid by in the cutting of a canal.

SPOILS, SPOLIA, whatever is taken from an enemy in war. See BOOTY.

Towns and lands taken from the enemy are uſually called "conqueſts;" and all moveable things conſtitute the "booty." This booty naturally belongs to the ſovereign making war, no leſs than the conqueſts; for he alone has ſuch claims againſt the enemy as warrant him to ſeize on his goods, and appropriate them to himſelf. His ſoldiers, and even the auxiliaries, are only inſtruments in his hand for aſſerting his right. He maintains and forms them. Whatever they do is in his name, and for him. Thus there is no difficulty even with regard to the auxiliaries; if they are not aſſociates in the war, it is not made for them, they have no more right to the booty than the conqueſts. But the ſovereign may grant the troops what ſhare of the booty he pleaſes. At preſent, moſt nations allow them whatever they can make on certain occaſions, when the general allows of plundering what they find on enemies fallen in the field of battle, the pillage of a camp which has been forced, and ſometimes that of a town taken by aſſault. The ſoldier in ſeveral ſervices has alſo the property of what he can take from the enemy's troops when he is on a party, or in a detachment, excepting artillery, military ſtores, magazines, and convoys of proviſion or forage, which are applied to the wants and uſe of the army. This cuſtom being once admitted in an army, it would be injuſtice to exclude auxiliaries from the right allowed to the national troops. The Roman ſoldier was obliged to bring in all the booty he had taken to the public ſtock. This the general cauſed to be ſold, and after diſtributing a part among the ſoldiers, according to rank, the reſt was conſigned to the public treaſury.

Inſtead of the pillage of the country and defenceleſs places, a cuſtom has been ſubſtituted more humane, and more advantageous to the ſovereign making war; *viz.* that of contributions. Whoever carries on a juſt war, has a right of making the enemy's country contribute to the ſupport of the army, and towards defraying all the charges of the war. Thus he obtains a part of what is due to him, and the ſubjects of the enemy, on ſubmitting to this impoſition, are ſecured from pillage, and the country is preſerved. But a general who would not ſully his reputation, is to moderate his contributions, and proportion them to thoſe on whom they are impoſed. An exceſs in this point is not without the reproach of cruelty and inhumanity: if it ſhews leſs ferocity than ravage and deſtruction, it glares with avarice. If for weakening an unjuſt enemy, or for puniſhing him, it be lawful to carry off his goods, which is allowed to be the caſe, the reaſons that juſtify the former act, may alſo be pleaded in vindication of deſtroying what cannot conveniently be carried off. Thus a country is ravaged, the proviſions or forage deſtroyed, that the enemy may not find a ſubſiſtence there. When his ſhips cannot be taken or brought off, endeavours are uſed to ſink them; all this tends to put an end to the war. But theſe means are to be uſed only with moderation, and according to the exigency. To tear up vines, or cut down fruit-trees, is accounted illegal and ſavage, except inflicted to puniſh ſome crime committed by the enemy againſt the laws of war. This is to deſolate a country for many years, and what no ſafety can require. Such a conduct is not dictated by prudence, but by hatred and fury.

However, on certain occaſions, matters are carried ſtill farther; a country is totally ravaged, towns and villages are ſacked, ſet on fire, and the inhabitants put to the ſword. Dreadful extremity, even when forced to it! Savage and monſtrous exceſſes, when committed without neceſſity! However, they are authoriſed by two reaſons. 1. The neceſſity of chaſtiſing an unjuſt and barbarous nation, for checking its brutality, and preſerving one's ſelf from its depredations. 2. A country is ravaged, and rendered uninhabitable, for making a barrier, in order to cover a frontier againſt an enemy, who cannot be ſtopped in any other way. A hard reſource indeed! ſays Vattel; but may it not be uſed againſt an enemy, when with the ſame views and purpoſes a ſovereign lays waſte his own provinces? But for whatever cauſe a country be ravaged, we ought to ſpare thoſe edifices which do honour to human ſociety, and do not contribute to the enemy's power; ſuch as temples, tombs, public buildings, and all works of a remarkable beauty. What advantage is obtained by deſtroying them? He who acts thus declares himſelf an enemy to mankind, wantonly depriving them of theſe monuments of art and models of taſte. This is the light in which Beliſarius repreſented it to Tottila, king of the Goths. We ſtill deteſt thoſe barbarians for deſtroying ſo many wonders of art, when they over-ran the Roman empire. Though the reſentment of the great Guſtavus againſt Maximilian, duke of Bavaria, was entirely juſt, he rejected with indignation the advice of thoſe who were for demoliſhing the ſtately palace of Munich; and took particular care to preſerve that admirable ſtructure.

However, if for carrying on the operations of a war, or the works of a ſiege, there be a neceſſity for deſtroying buildings of this nature; there is doubtleſs a right of ſo doing. The ſovereign of the country, or his general, makes no ſcruple when reduced to it by neceſſity and maxims of war. The governor of a town evidently threatened with a ſiege, ſets fire to the ſuburbs, that they may not be of uſe to the beſiegers for lodging themſelves in them. Nobody offers to blame him who lays waſte gardens, vineyards, or orchards, for pitching a camp or throwing up an intrenchment; if ſome fine edifice be deſtroyed thereby, it is an accident, an unhappy conſequence of the war, and the general is not at all blameable; unleſs, without the leaſt inconveniency, he might have made his diſpoſitions elſewhere.

In bombarding towns, it is difficult to ſpare the fine edifices; at preſent it is only the ramparts and defences of a place which are uſually battered. To deſtroy a place with bombs and red-hot balls, is an extremity never practiſed without great reaſons. But it is warranted by the laws of war, when an army has no other reſource for reducing a place on which may depend the ſucceſs of the war, or when it greatly annoys us. It is alſo ſometimes practiſed when there is no other expedient of facing an enemy to make war with humanity, or for puniſhing him for ſome other illegal outrage. But it is with reluctance that good princes make uſe of their rigorous rights, and never but in extremities.

Fortreſſes, ramparts, and every kind of fortification, relate ſolely to war, and as in a juſt war nothing is more natural than to raze thoſe which we do not intend to keep, ſo nothing is more lawful. The enemy is thereby weakened, and no innocent perſon is involved in the damages.

Although to ravage or burn a country is not in general againſt the laws of war, yet if an enemy of a much ſuperior ſtrength treats a town or province in this manner, which he might eaſily keep for procuring to himſelf an equitable and advantageous peace, he is generally accuſed of making war like a barbarian. Thus the voluntary deſtruction of public monuments, of temples, tombs, ſtatues, paintings, &c. is abſolutely condemned, even by the voluntary law of nations, as always uſeleſs to the lawful end of war. The pillage and deſtruction of towns, the deſolation of the country, ravages, burnings, are not leſs odious and deteſted on all occaſions, when evidently practiſed without neceſſity, or without urgent reaſons. But as all theſe enormities may be excuſed under pretence of puniſhment, which the enemy deſerves, Vattel adds, that by the neutral and voluntary law of nations, only enormous offences againſt it are to be puniſhed in this manner: and when rigour is not of an abſolute neceſſity, it is always beautiful to liſten to the voice of humanity and clemency. Cicero condemns the deſtruction of Corinth for its inſults towards the Roman ambaſſadors; becauſe Rome was able to aſſert the dignity of its miniſters, without carrying its revenge to ſuch extreme rigour. Vattel's Law of Nations, b. iii. ch. 9.

SPOKEN-CHAIN, in *Rural Economy*, ſignifies provincially a chain of great ſtrength, and ſufficiently long for fixing upon the ſpoke of the wheel of a waggon, when the team is ſet faſt in a ſlough, to draw it out by, &c.

SPOKES, the bars of a wheel that paſs from the nave to the felly.

SPOKE-SHAVE, in *Block-making*, a kind of plane to ſmooth and finiſh the ſhells, which is a piece of ſteel, four or more inches long, and one and a half broad; ſharp at one edge as a knife, and a quarter of an inch thick at the back: at each end are left about two inches of narrow ſteel, bent up as pegs, by which it is regulated and ſecured in a piece of wood ten inches long, and narrowed at each end, for handles.

SPOLETO, in *Geography*, capital of Umbria, or the duchy of Spoleto, the ſee of a biſhop, immediately under the pope. It became a Roman colony A. U. C. 512; and 22 years afterwards, withſtood the forces of Hannibal, after the battle near the Thraſymene lake. It was the reſidence of ſome of the Gothic kings, and under the government of Longinus, exarch of Ravenna, was made the capital of Umbria, with the title of duchy. It was very ill-treated by Frederic Barbaroſſa, for ſiding with pope Alexander III.; but the inhabitants of Perugia ruined it entirely. It contains 22 churches, 21 convents, and 17 hermitages. Here are ſeveral ruins of Roman antiquities, the chief of which are a triumphal arch, an aqueduct, and an amphitheatre. The cathedral is built almoſt entirely of marble, and contains ſome good pictures; 90 miles S. of Florence. N. lat. 42° 45′. E. long. 12° 48′.

SPOLETO, *Duchy of*, a province of the Popedom, bounded on the north by the Perugiano and the duchy of Urbino, on the eaſt by the marquiſate of Ancona, on the ſouth by Abruzzo Ultra and the Sabina, and on the weſt by the Orvietan and Patrimonio, about 40 miles in length, and nearly as much in breadth. It was anciently called *Umbria*, and received the name of Spoleto in the time of the Lombards, being erected into a duchy under duke Faroald. On the extinction of the Longobardian monarchy, it fell to the dominion of the Franks, ſtill retaining its former conſtitution, and afterwards was annexed to the papal territories. In 1798 this duchy was over-run by the French.

SPOLIARIUM, among the ancient *Romans*, the third part of the bath, uſed for undreſſing and dreſſing in.

Spoliarium was likewiſe a part of the gladiatorial ſchools, where their clothes and ornaments were laid, and where the wounded and killed were carried.

SPOLIATION, in *Law*, is an injury done by one clerk or incumbent to another, in taking the fruits of his benefice without any right to them, but under a pretended title. It is remedied by a decree to account for the profits ſo taken. This injury, when the *jus patronatus*, or right of advowſon, does not come in debate, is cognizable in the ſpiritual court; as if a patron firſt preſents A. to a benefice, who is inſtituted and inducted to it; and then, upon pretence of a vacancy, the ſame patron preſents B. to the ſame living; and he alſo obtains inſtitution and induction. Now, if A. diſputes the fact of the vacancy, then that clerk who is kept out of the profits of the living, whoever he be, may ſue the other in the ſpiritual court for ſpoliation, in taking the profits of his benefice. And it ſhall there be tried, whether the living were, or were not vacant; upon which the validity of the ſecond clerk's pretenſions muſt depend. But if the right of patronage comes at all into diſpute, as if one patron preſented A., and another patron preſented B., there the eccleſiaſtical court hath no cognizance, provided the tithes ſued for amount to a fourth part of the value of the living, but may be prohibited at the inſtance of the patron, by the king's writ of *indicavit*. So alſo if a clerk, without any colour of title, ejects another from his parſonage, this injury muſt be redreſſed in the temporal courts: for it depends upon no queſtion determinable by the ſpiritual law (as plurality of benefices or no plurality, vacancy or no vacancy), but is merely a civil injury. Blackſt. Comm. b. iii.

SPOLTORA, in *Geography*, a town of Naples, in Abruzzo Ultra; 12 miles S.E. of Teramo.

SPONDAULA, σπονδαυλης, formed from σπονδη, *libation*, and αυλος, *flute*, in *Antiquity*, a player on the flute, or other wind-inſtrument of that kind; who, during the offering of ſacrifice, performed ſome ſuitable air in the prieſt's ear, to prevent his hearing any thing that might diſtract him, or leſſen his attention.

SPONDE, HENRY DE, in *Biography*, a French prelate and eccleſiaſtical hiſtorian, was born in 1568. His father was ſecretary to Joan, queen of Navarre, and, being a Calviniſt, educated his ſon in the ſame perſuaſion. He diſplayed, at a very early age, a great facility in learning languages, one of which was the native tongue of Scotland, which he acquired in a journey to that kingdom in the ſuite of the French ambaſſador. Upon his return, he ſtudied the civil and canon law, and was made maſter of requeſts to the king of Navarre. In 1595 he abjured Proteſtantiſm, and in the following year declared his new opinions in a work, "De Cœmeteriis Sacris." In the year 1600, he accompanied cardinal de Sourdis to Rome, and ſome years after he was ordained prieſt. He then began to labour on his great work, *viz.* the "Abridgment of the Annals of Cardinal Baronius," to which has been added a "Continuation," brought down to 1640. In 1626 he was nominated by Louis XIII. to the biſhopric of Pamiers, which he accepted only through the command of pope Urban VIII. He publiſhed "Ordinances Synodales," which were intended to aſſiſt in the converſion of his former aſſociates. He alſo founded an eccleſiaſtical congregation, ſome ſeminaries and religious houſes, and diſtinguiſhed himſelf by all the epiſcopal virtues. He died at Toulouſe in 1643, at the age of 78. Beſides the works mentioned above, he publiſhed "Sacred Annals of the Old Teſtament to the Time of Jeſus Chriſt," which are, properly ſpeaking, an abridgment of Tormiel's Annals. His elder brother was author of "Commentaries on Homer;" "An Account of the Motives which induced him to unite himſelf with the Catholic Church;" and "An Anſwer to Beza's Treatiſe on the Marks of the Church." He died in the year 1595.

SPONDEE, SPONDÆUS, in the *Greek* and *Latin Proſody*, a foot of verſe, conſiſting of two long ſyllables; as *vertunt*, *divos*, *campos*.

The ſpondee is a grave meaſure: all Greek and Latin hexameters regularly end with a ſpondee.

There are alſo *ſpondaic verſes;* that is, verſes compoſed wholly of ſpondees, or, at leaſt, that end with two ſpondees; as,

"Conſtitit, atque oculis Phrygia agmina circumſpexit."

SPONDIAS, in *Botany*, a name borrowed from the ancient Greeks, whoſe σπονδιας, or σποδιας, was a kind of wild plum, very diſtinct, moſt aſſuredly, from the preſent Indian genus, though there may be ſome ſimilarity in their fruits.—Linn. Gen. 229. Schreb. 308. Willd. Sp. Pl. v. 2. 750. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 108. Juſſ. 372. Lamarck Illuſtr. t. 384. Gærtn. t. 103. (Monbin; Plum. Gen. 44. t. 22.)—Claſs and order, *Decandria Pentagynia*. Nat. Ord. uncertain, Linn. *Terebintaceæ?* Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, ſomewhat bell-ſhaped, ſmall, five-cleft, coloured, deciduous. *Cor.* Petals five, oblong, flat, ſpreading. *Stam.* Filaments ten, awl-ſhaped, erect, ſhorter than the corolla, the alternate ones longer; anthers oblong. *Piſt.* Germen ovate; ſtyles five, ſhort, diſtant, erect; ſtigmas obtuſe. *Peric.* Drupa large, oblong, marked with five ſcars from the fall of the ſtyles. *Seed.* Nut ovate, woody, fibrous, with five imperfect angles, and five cells.

Obſ. Juſſieu remarks, that the ſtamens are inſerted into a glandular diſk; or, in Linnæan language, receptacle of the flower; probably a nectary.

Eſſ. Ch. Calyx five-toothed. Petals five. Drupa ſuperior, with a nut of five cells.

1. S. *Mombin*. Spaniſh Plum. Linn. Syſt. Nat. ed. 10. v. 2. 1036. Syſt. Veg. ed. 14. 428. Willd. n. 1. (S. purpurea; Linn. Sp. Pl. 613. S. Myrobalanus; Jacq. Amer. 139. t. 88. S. n. 1; Browne Jam. 228. Myrobalanus minor, folio fraxini alato, fructu purpureo, oſſiculo magno fibroſo; Sloane Jam. v. 2. 126. t. 219. f. 3—5.) Common footſtalk compreſſed. Cluſters much ſhorter than the leaves.—Obſerved by Jacquin to be wild in the territory of Carthagena, South America, from whence it has been brought into the Weſt Indian iſlands, in ſome of which, particularly Hiſpaniola and Jamaica, it abounds, being known by the name of the Spaniſh Plum-tree. The *tree* is various in height, of no regularity of growth, ſometimes as tall as thirty feet, with a thick bark, and white brittle wood. *Leaves* about the ends of the branches, alternate, ſtalked, deciduous, pinnate, four or five inches long, of about ten pair of elliptical ſhining, partly ſerrated, leaflets, an inch long, with an odd one of the ſame ſize. *Flowers* ſmall, red, in ſhort cluſters, appearing before the leaves. *Fruit* ovate, purple, above an inch long, acid, with a ſingular but agreeable aromatic flavour, for which it is much eſteemed.

2. S. *Myrobalanus*. Yellow Hog Plum. Linn. Syſt. Nat. ed. 10. v. 2. 1036. Willd. n. 2. Ait. n. 1. (S. lutea; Linn. Sp. Pl. 613. S. Mombin; Jacq. Amer. 138. S. n. 2 and 3; Browne Jam. 229. Myrobalanus folio fraxini alato, fructu luteo, oſſiculo magno fibroſo; Sloane Jam. v. 2. 125. t. 219. f. 1, 2. Prunus americana; Merian Surin. t. 13.)—Common footſtalk round. Leaflets pointed, four or five pair. Cluſters compound, about as long as the leaves.—Native of South America; cultivated in the Weſt Indies. Miller had it alive at Chelſea in 1739. This is deſcribed as a *tree* reſembling a common Walnut-tree in ſize and appearance, while the ample cluſters of pale yellowiſh *flowers* are much like Elder, except in having no ſmell. The *leaves* are twice the ſize of the foregoing, with pointed, leſs ſerrated, leaflets. *Fruit* yellow, two inches long, in large cluſters, its pulp fragrant, ſweet, and agreeable, but the great ſize and fibrous nature of the ſtones render it not commodiouſly eatable. Hogs are fattened with theſe plums in Jamaica. We cannot but obſerve that Linnæus has changed his own original names of theſe two ſpecies, much for the worſe; and thoſe he has given are the more unfortunate, as they are directly contrary to what Jacquin had previouſly adopted.

3. S. *Mangifera*. Eaſt Indian Spondias. Willd. n. 3. (S. amara; Lamarck Dict. v. 4. 261. Mangifera pinnata; Linn. Suppl. 156. Retz. Obſ. faſc. 5. 4. Ambalám; Rheede Hort. Malab. v. 1. 91. t. 50, not 51.)—Common footſtalk round. Leaflets entire, pointed, about three pair. Cluſters repeatedly compound.—Native of the Eaſt Indies, flowering in January and July, and bearing two crops of fruit. This is difficult to diſtinguiſh by a ſpecific character from the laſt, though widely different in many reſpects. That they are one genus, there can be no doubt. The *trunk* is a foot in diameter. *Leaves* of three pair, beſides an odd one, of elliptical, pointed, entire, ſmooth, pliant leaflets, each four or five inches long, with one rib, and many parallel tranſverſe veins. Rheede ſays they are agreeably acid. *Cluſters* hardly ſo long as the leaves, thrice compound; their principal branches alternate, widely divaricated, ſmooth, purpliſh; flower-ſtalks crowded, bracteated, very ſhort, but much elongated and ſpreading when in fruit. *Flowers* ſmall and pale, ſometimes ſix-cleft. *Fruit* oval, of a yellowiſh-green, an inch and a half long, eatable and agreeably fragrant. The *Cat-Ambalám*, Rheede p. 93, ſeems to be the wild ſtate of the ſame tree.

4. S. *dulcis*. Otaheité Apple. Forſt. Prod. 34. Pl. Eſc. 33. Willd. n. 4. Ait. n. 2. (S. cytherea; Sonnerat Ind. Or. v. 2. 222. t. 123. Lamarck Dict. v. 4. 260. Jacq. Hort. Schoenbr. v. 3. 12. t. 272.)—Common footſtalk round. Leaflets ſerrated, about ſix pair. Cluſters repeatedly compound, ſpreading.—Native of Otaheité, from whence it has been tranſported to the Mauritius, where alſo the laſt-deſcribed ſpecies is cultivated, as appears by ſpecimens from Commerſon marked *Evia Amra;* for he diſtinguiſhed the two. The preſent is a large erect *tree*, with brittle wood. Its *leaflets* are ſerrated, twice as numerous, and not half the ſize of the laſt. *Flowers* ſmall, whitiſh. *Fruit* oval, orange-coloured, twice as big as the laſt, aromatic and eatable, reſembling an apple in flavour, and by ſome voyagers much commended. Forſter compares its taſte to a pine-apple, and praiſes its ſalubrity. Sonnerat ſays it is like a rennet apple, but not ſo good; at leaſt in the Mauritius.—This fruit has ripened in the ſtoves at Schoenbrun.

SPONDIAS, in *Gardening*, contains plants of the exotic tree kind, of which the ſpecies cultivated is the purple hog-plum, or Spaniſh plum (S. mombin).

This plant is cultivated in its native ſtate by many for the ſake of the fruit, which is pretty pleaſant. And there is a variety of this ſort of fruit called the leather-coat, from the appearance of its ſkin.

Method of Culture.—It is increaſed by ſowing the ſtones of the fruit in pots filled with light mould, plunging them in the bark-bed of the ſtove; and by planting, cuttings, or putting down layers, and managing them in the ſame way: the plants may be taken off and removed into ſeparate pots when they have ſtricken good roots, being re-plunged in the bark-bed.

They require afterwards to be kept conſtantly in the ſtove, and to have the ſame management as other woody exotics of the ſame nature.

They afford variety in ſtove collections among other ſimilar plants.

SPONDYLI, Σπονδυλοι, in *Antiquity*, pellets of braſs uſed in giving ſentence, before the κυαμοι, or *beans*, came into uſe.

SPONDYLOLITHOS, a name given by authors to a ſtone found in the country of Tyrol, and elſewhere, reſembling the vertebræ of an animal. It is in reality no other than the vertebræ of ſome ſea-fiſh petrified, as is common with us.

SPONDYLUS, σπονδυλος, a term anciently uſed for a vertebra of the ſpina dorſi.

Spondylus, in *Natural Hiſtory*, a genus of the claſs and order Vermes Teſtacea, of which the generic character is: Animal a tethys; ſhell hard, ſolid, with unequal valves; one of the valves is convex, the other rather flat; hinge with two recurved teeth, ſeparated by a ſmall hollow. There are four

Species.

Gædaropus. The ſhell of this ſpecies is ſlightly eared and ſpinous. It inhabits the Mediterranean, the Indian, and other ſeas, and is found in almoſt infinite varieties, as to ſize, thickneſs, and colours; ſometimes entirely purple, orange, white, or bloom-colour; ſometimes marked with various ſtreaks, ſpots, dots, or bands.

Regius. Shell without ears, and ſpinous. There are four varieties. One inhabits India, and one is found near Malta, which is very rare. The ſhell is ſub-globular; within it is white; without purpliſh, ſcarlet, flame-coloured, orange or white; the ſpines are uſually two inches long; it is ſometimes cylindrical, with a crenate margin.

Plicatus. Shell without ears or ſpines, plaited. It is found in India, ſome parts of America, and in the Mediterranean. The ſhell is white, with yellowiſh, reddiſh, browniſh, or violet lines and veins.

Citreus. Shell oblong, plaited, ſpinous. The ſhell is imbricate, about two inches long, and nearly as broad; it is of a citron-colour, or red, with an orange inner margin.

SPONGE. See **Spongia** and **Spunge**.

Sponge-*Tree*, in *Botany*. See **Mimosa**.

SPONGIA, *the Spunge*, in *Natural Hiſtory*, a genus of the claſs and order Vermes Zoophytes. The generic character is as follows: Animal fixed, flexile, torpid, of various forms, compoſed either of reticulated fibres, or maſſes of ſmall ſpines, interwoven together, and clothed with a gelatinous fleſh, full of ſmall mouths on its ſurface, by which it abſorbs and rejects water. There are about fifty ſpecies, of which nine or ten belong to this country.

The ſponges conſiſt of a ramified maſs of capillary tubes, that were formerly ſuppoſed to be the production of a ſpecies of worms, which are often found within theſe cavities; an idea, however, which is now generally exploded. Others have imagined them to be only vegetable productions: that they are, however, poſſeſſed of animality, appears evident, from the circumſtance of their pores alternately contracting and dilating, and from their even ſhrinking, in ſome degree, from the touch, when examined in their native ſituations. Their ſtructure enables them, it is thought, to abſorb nouriſhment from the ſurrounding fluid. Sponges are the moſt torpid of all the zoophytes. The individuals differ very much from each other in form and ſtructure. Some of them, as the S. officinalis, or common ſponge, are of no determinate figure, but others are cup-ſhaped, tubular, &c.; irregularly formed, porous, rough, lobed, and woolly.

Species.

Ventilabrum. Fan-ſhaped, regular, ſoft, with reticulate woody veins, covered with pores like thoſe of a honey-comb. It is found in the Norwegian and American ſeas; about ſix inches high, and five broad: it exactly reſembles a ſmall gorgonia flabellum in its ſhape and ramifications, except that the pores are angular, and the ſubſtance is ſpongy.

Flabelliformis. Fan-ſhaped, orbicular, cartilaginous, with ſquare articulate fibres. This ſpecies inhabits the Indian and Red ſeas. It is from ſix to eight inches in height, and four or five broad, and reſembles the ventilabrum.

Infundibuliformis. This is funnel-formed, flexile, with the ſurface more or leſs roughened. It inhabits the Mediterranean and Indian ſeas, adhering to rocks, and is from ſix to eighteen inches in diameter; in colour it is a pale brown, and leſs tenacious than common ſponge.

Fistularis. Tubular, ſimple, brittle, and growing gradually larger. It inhabits the Indian ocean, is from three to four feet long: when dry it is blackiſh fulvous.

Aculeata. Tubular, branched, tough, the tubes erect, proceeding from one ſide of the ſtem, and tapering. It inhabits the Indian ocean; is from four to ſix inches high, of a deep orange-yellow colour, and hollow through the whole inſide.

* **Coronata.** Minute, conſiſting of a ſingle tube, and crowned at the tip with a ray of ſpines. This is found in our own country, on the Suſſex coaſt: its colour is of a pale yellow; the rays that compoſe the crown are of a bright pearl yellow, hollow, and open at the top; and when ſeen through a magnifier, it appears covered with little riſing points.

Ciliata. Simple, tubular, conic, flexuous, tapering upwards, and fringed at the tip. It inhabits the Greenland ſeas, adhering to the larger ulvæ; is about eight inches long; white, ſilky, downy on the outſide, and rarely found double.

Cancellata. Tubular, porous, with cancellate fibres. It inhabits the ocean; is ferruginous, elaſtic, with a prickly ſurface; the tube as thick as the finger, with a few elaſtic perforations.

Rubra. Tough, ſimple, carious, dull red, roundiſh, depreſſed with elevated tubercles and equal pores. Inhabits the Red ſea, fixed to ſtones.

Nigra. Tough, globular, equal, inflated, black without, cinereous within. It is found on rocks in the Red ſea.

Officinalis. This ſpecies is irregularly formed, porous, tough, lobed, woolly. It is elaſtic, and very full of holes; it grows into irregular lobes of a woolly conſiſtence, and generally adheres, by a very broad baſe, to the rocks. It is chiefly found about the iſlands in the Mediterranean, where it forms a conſiderable article of commerce. A variety of ſmall marine animals pierce and gnaw into its irregular winding cavities. Theſe appear on the outſide, by large holes raiſed higher than the reſt. When it is cut perpendicularly,

cularly, the interior parts are ſeen to conſiſt of ſmall tubes, which are divided into branches as they appear on the ſurface. Theſe tubes, which are compoſed of reticulated fibres, extend themſelves every way, by this means increaſing the ſurface of the ſponge, and ending at the outſide in an infinite number of ſmall circular holes, which are the proper mouths of the animal. Each of theſe holes is ſurrounded by a few erect pointed fibres, that appear as if woven in the form of little ſpines. The tubes, with their ramifications, in the living ſtate of the ſponge, are clothed with a gelatinous ſubſtance, properly called the fleſh of the animal. When the ſponge is firſt taken, it has a ſtrong fiſhy ſmell, and the fiſhermen take great care in making it perfectly clean, in order to prevent its growing putrid. See Spunge.

* **Oculata.** Porous, ſoft, and very much branched, the branches a little compreſſed, erect, and often uniting together. This, as the aſteriſk indicates, inhabits the Britiſh ſeas. It is from five to ten inches high, of a pale yellow colour; the branches end obtuſely.

Muricata. Porous, much branched, angular, tough, the pores are cylindrical, ſubulate, prominent, equal, many-cleft, and hiſpid. It inhabits Guinea, on rocks; it is grey, corky; the branches are ſurrounded on all ſides with ſmall, obtuſe, ſhaggy tufts; the ſtem is as thick as a man's finger; the branches are about the thickneſs of a quill.

Nodosa. Porous, ſlightly branched, irregularly formed, rough and very tough, with knotty perforations on the branches. It is found on rocks in the American ocean; it is of a reddiſh-grey, or whitiſh, and about the ſize of the finger.

* **Tomentosa.** Porous, irregularly formed, brittle, ſoft, downy, interwoven with the minuteſt ſpines. This ſpecies inhabits the Britiſh, African, and Indian coaſts, adhering to marine ſubſtances; when freſh it is of a bright orange colour, and full of gelatinous fleſh; when dry, it is whitiſh, and very light; and if broken, it reſembles the crumb, or ſoft part of bread. It appears to be compoſed of a number of minute ſpines, and upon handling, it ſtings and raiſes bliſters like cow-itch.

Bacillaris. Irregularly formed, caulescent, erect, with porous branches. It is found in the Norwegian ſeas; is about eighteen inches high, and of the thickneſs of the finger. It is round, of the conſiſtence of common ſponge, but ſomewhat more compact, with very numerous pores, appearing as if perforated with a fine needle.

* **Dichotoma.** This ſpecies is dichotomous, with erect, cylindrical, elaſtic, woolly branches, proceeding from one ſide of the ſtem. It inhabits European and Indian ſeas: is from five to ſix inches high; in colour it is of a pale yellow, and full of minute pores.

* **Stuposa.** This ſpecies has round, ſoft, downy branches. It is found on the Suſſex coaſt; is three inches high, and of a pale yellow.

* **Cristata.** Flat, erect, ſoft, with rows of ſmall pores, a little projecting along the top. This is found on the Britiſh ſhores, adhering to rocks; generally about two inches high and three long; it is of a yellowiſh colour, and growing in the ſhape of a cock's-comb.

* **Palmata.** This ſpecies is, as its name imports, palmate, with finger-like diviſions round the ſurface; the pores are a little prominent, and irregularly diſpoſed. It inhabits the Suſſex coaſt; it is of a reddiſh colour, inclining to yellow, with a ſoft woolly ſubſtance, like S. oculata.

Prolifera. Flat, with numerous palmate branches, ending in finger-like diviſions. It is found in the North American ſeas; grows in large bunches, is about ſix inches high, very porous, reticulate within, and full of minute ſpines on the outſide.

* **Botryoides.** This is a very tender ſpecies, is branched, and covered with bunches of ovate tubercles, open at the top. It inhabits the Britiſh coaſts; is of a bright ſhining white colour; the bunches are made up of oblong, oval tubercles, like grapes, open at the end. The ſurface, when ſeen through magnifiers of conſiderable power, ſeems covered with maſſes of three-rayed ſpinous ſtars.

* **Panicea.** Irregularly formed, whitiſh, ſoft, very tender, and full of minute pores. It inhabits the ſeas between this country and Holland, intermixed with fuci, and other marine productions; and is thought, from the ſimilarity which it bears to the S. tomentoſa, to be a variety of that ſpecies.

Fulva. This ſpecies is irregularly formed, but ſlightly branched, fulvous, and it is very rigid. It inhabits the American ocean; is gelatinous, and brown between the fibres.

Tabularia. Compreſſed, ſeſſile, a little rigid and yellowiſh, with ſmall longitudinal tubes. This alſo is an American ſpecies, generally ſeated on rocks, frequently blackiſh within.

Fibrillosa. This ſpecies is irregularly ſhaped, a little flattened and tender, with divergent, crowded, interwoven fibres, and ſcattered toothed pores. It inhabits the Indian ocean, is grey, ſoft, fan-ſhaped, or divided, or caulescent.

Fasciculata. This is rigid, ſub-globular, compoſed of fibrous, priſmatic, branched, faſtigiate bunches. This is found in the Mediterranean ſea; is pale, fulvous, or yellowiſh-grey.

Basta. A little rigid, blackiſh, in undulate diviſions, with a round ſtem. It is an inhabitant of the Indian ocean, and found adhering to ſtones. It is as thick as the finger.

Lichenoides. This is irregularly ſhaped, with ſoft, branching, ſcattered, and ſomewhat connected fibres. It inhabits the Indian ocean, and reſembles a ſhrubby lichen.

Papillaris. Cruſtaceous, tender, ſoft, with perforated papillæ. It inhabits the American ocean, as does the next; it is of a pale grey, and gelatinous.

Cavernosa. Irregularly formed, ſeſſile, very tough, cavernous, hence its name, with numerous, prominent papillæ on the ſurface. It is about the ſize of a man's hand: yellowiſh-white, ſometimes fulvous within.

Sinuosa. Cruſtaceous, tender, tough, with a thickly porous ſurface. This is found in the Indian ocean, incruſting other bodies; it is of a yellowiſh-grey colour.

Frondosa. Grey, leafy, jagged, tough, ſub-reticulate, and ſeparated into diviſions on one ſide. This is an Indian ſpecies.

Agaricina. Compreſſed, lobed, ſeſſile, downy, reticulate and muricate with ſtiff hairs on the outſide. It is found in the Indian ocean, and is of a yellowiſh-brown.

Tupha. Branched, ſoft, with aſcending branches, every where muricate with ſtiff hairs. It inhabits the Mediterranean, and is of a woolly kind of ſubſtance.

Membranosa. Irregularly formed, ſlightly branched, cellular, muricate outwardly, purpliſh-black. This is found in the Indian ocean.

Compressa. Simple, compreſſed, conic, with a longitudinal cleft or aperture internally. It inhabits the Greenland ſeas, is an inch long; erect and tawny.

Porcillum. Cylindrical, pedicillate, with a perforated top. It inhabits the North ſeas; is not more than a quarter of an inch long; whitiſh, and ſaid to reſemble a glaſs tumbler.

Coalita. This is very much branched, ſoft, tender, yellow; the branches are a little compreſſed. It inhabits the North ſeas; as do the three following.

Plana. Expanded, cruſtaceous, fan-ſhaped.

Cruciata. White, compreſſed, with pinnatifid, obtuſe, muriate, woolly branches.

Ossiformis. White, ſlightly branched, with a thickened pitted top.

Macida. White, cruſtaceous, projecting into ſpines.

Ficiformis. This is porous, rigid, turbinate, with a perforated tip. It inhabits the Barbary coaſt.

* Lacustris. Creeping, brittle, with erect, round, obtuſe branches. It is found at the bottom of lakes in England and Sweden, covered with ſcattered pores, in which are ſometimes found, during autumn, ſmall blueiſh ſhining globules.

* Pulviatilis. Green, erect, fragile, of many irregular branches. It inhabits the freſh waters of this country, Pruſſia, and other parts of Europe. It is of a dull green, with hardly the appearance of animal life, of a fiſhy ſmell, and with the pores full of green, gelatinous granulations; it very much reſembles the laſt.

Friabilis. Cinereous, friable, ſeſſile, irregularly ſhaped, and ſlightly branched. Found in the lakes of Germany, and is the food of fiſh.

Canadium. This is known by its dichotomous, round, incurved branches. It is found in old aqueducts, and has been thought not to belong to this genus.

SPONGIOLI, a word uſed by ſome authors to expreſs the ſmall button muſhrooms, which are gathered before they expand or open their heads.

SPONGIOSUM, in *Anatomy*, ſpongy; a name given to a ſmall ſeparate bone of the noſe, and to a proceſs of the ethmoid bone. In the older writers, the ethmoid bone altogether has been called os ſpongioſum, from its complicated apparatus of bony plates, and numerous perforations. See Cranium.

SPONGY Cheese, in *Rural Economy*, ſuch as is ſoft and full of eyes, from neglect and want of attention in making. The remedies are, careful breaking, powerful ſqueezing, good ſkewring, and heavy preſſing. See Cheese and Dairying.

SPONHEIM, in *Geography*, a town of France, in the department of the Rhine and Moſelle, late capital of a county, to which it gives name; 27 miles W. of Mentz. N. lat. 49° 54′. E. long. 7° 40′.

Sponheim, or *Spanheim*, late a county of Germany, in the circle of the Upper Rhine, ſituated between the Rhine and the Moſelle, formerly governed by particular counts, at preſent divided between the elector palatine, the duke of Deux Ponts, and the margrave of Baden. The matricular aſſeſſment of the whole for a Roman month was 290 florins, and the tax to the imperial chamber 108 rix-dollars 20 kruetzers. The ſoil is in general mountainous, but fertile. Game and fiſh are plentiful, and the mutton eſteemed excellent. The hills towards the Moſelle and Nahe are covered with vineyards. Here are mines of copper, lead, iron, &c. and ſome medicinal ſprings. The principal towns were Cruetznach, Sponheim, and Traarbach; all now annexed to France

SPONSIO, in *Political Economy*, denotes an agreement relating to affairs of ſtate, made by a public perſon, who goes beyond the terms of his commiſſion, and acts without the orders or commands of the ſovereign. He who treats in this manner for the ſtate, without having a commiſſion, promiſes by this means to take ſuch meaſures, that the ſtate, or the ſovereign, ſhall approve and ratify the agreement; otherwiſe his agreement would be vain and illuſive. The foundation of this agreement can be no other, on either ſide, than the hope of the ratification. The Roman hiſtory furniſhes examples of this kind of agreements.

Sponsio *Judicialis*, in *Law*. See *Feigned* Issue.

SPONSORS. See God-fathers.

SPONSUS, one of the many names given by the chemiſts to mercury.

SPONTANEOUS, Spontaneus, formed from the Latin adverb *ſponte*, *of one's own accord*, in the *Schools*, a term applied to ſuch motions of the body and mind as we perform ourſelves without any conſtraint.

Thus, in morality, thoſe actions performed upon an inward and natural principle, conformable to our own inclinations, excluding all conſtraint, are called ſpontaneous actions.

In medicine, an evacuation, effected without any application for that purpoſe, is called a ſpontaneous evacuation. And a laſſitude or wearineſs, not occaſioned by any preceding fatigue, is called a ſpontaneous wearineſs.

Spontaneous *Generation*. See Equivocal *Generation*.

Spontaneous *Precipitation*. See Precipitation.

SPONTOON, in *Military Language*, is a weapon reſembling a halberd, now uſed inſtead of a half-pike by the officers of foot. When the ſpontoon is planted, the regiment halts; when pointed forwards, the regiment marches; and when pointed backwards, it retreats.

SPOON-BILL, Platea, in *Ornithology*, the name of a bird of the long-necked kind, approaching to the nature of the ſtork and heron, and called the ſpoon-bill from the remarkable figure of its beak, which is different from that of all other birds, being broadeſt at the extremity, and terminating in a large, rounded, flat proceſs, reſembling a ſhovel; or, if it were hollow, a ſpoon. The whole bill of this bird is of a fine ſhining black, except a bright orange-coloured ſpot juſt above the point of the upper mandible, which is a little bent downward at its extremity; at the angles of the bill, on each cheek, there is alſo a ſpot of the ſame colour; the upper ſurface of the bill is elegantly waved with dotted protuberances; a depreſſed line, extending from the noſtrils, is continued round it near its edge; its ſubſtance appears like whale-bone, being thin, light, and elaſtic; the tongue is ſhort, and heart-ſhaped, and when drawn back, ſerves as a valve to cloſe the entrance of the throat; when pulled forward, it has the appearance of a triangular button; the ears are large, and placed an inch behind the angles of the mouth; the plumage of the whole body, wings, and tail, is white; on the back part of the head is a beautiful creſt of white feathers, hanging behind the neck; the legs are black, and alſo the thighs, which are naked about half their length; and the toes are connected by a ſmall web, extending to the firſt joint on each.

This bird breeds on high trees, feeds on fiſh and water-plants, and can ſwim; it inhabits the continent of Europe, South America, and the Philippine iſlands.

A flock of theſe birds migrated into the marſhes near Yarmouth in Norfolk, in April 1774. Pennant. See Platalea.

SPOON-DRIFT, in *Sea Language*, a ſort of ſhowery ſprinkling of the ſea-water, ſwept from the ſurface of the waves in a tempeſt, and flying according to the wind, like a vapour.

SPOONING, or Spooming, was formerly uſed to denote that movement in ſailing, which is now called *ſcudding*.

SPOON-WORT, in *Botany*. See Cochlearia.

SPORADES, in *Aſtronomy*, a name which the ancients gave to ſuch ſtars as were not included in any conſtellation.

Theſe the moderns more uſually call *informes*, or *extra-conſtellary ſtars*.

Many of the ſporades of the ancients have been ſince formed into new conſtellations; *e. gr.* of thoſe between Leo and Urſa major, Hevelius has formed a conſtellation, called *Leo minor;* of thoſe between Urſa minor and Auriga, the ſame perſon has formed another conſtellation, called *Lynx;* and of thoſe under the tail of Urſa minor another, called *Canis venaticus, &c.*

SPORADIC, *σποραδικος*, formed from *σπορας*, *diſperſed*, of *σπειρω*, *I ſtrew, &c.* in *Medicine*, an epithet given to ſuch diſeaſes as have ſome ſpecial or particular cauſe, and are diſperſed here and there, affecting only particular conſtitutions, ages, &c.

Sporadic ſtands in oppoſition to epidemic diſeaſes, which are thoſe ariſing from a general cauſe, and that are common to all kinds of perſons, of what complexion and quality ſoever.

SPORÆ, in *Botany*, from the Greek *σπορα*, *ſeed*, a name given by ſome botaniſts to the ſeeds of certain cryptogamic plants; by which they ſeem to imply a doubt of their being truly *ſemina*, or exactly analogous to the ſeeds of plants in general. We know not on what ſuch doubts are founded. If the parts in queſtion be produced or perfected by ſexual impregnation, they are to all intents and purpoſes real ſeeds, nor does any peculiarity, or apparent ſimplicity in their ſtructure, invalidate the propriety of their being ſo called. Seeds of different orders of phænogamous plants differ, as is well known, in their conformation, and even in the number of internal parts, as well as external coats, of which they are compoſed. Thoſe of the more obſcure cryptogamous tribes may therefore be expected to differ from them more widely. If ſuch apparent ſeeds be not the offspring of ſexual impregnation, they are GEMMÆ, ſee that article; where, as well as in our biographical account of the great HEDWIG, we have lamented that this diſtinguiſhed philoſopher and botaniſt ſhould have been ſeduced, by leſs accurate obſervers, to adopt a term entirely ſubverſive of his own doctrines and diſcoveries.

SPORANGIUM, from *σπορα*, *ſeed*, and *αγγος*, *a veſſel*, a name uſed by Hedwig for the capſule of moſſes, to which we have the ſame objection as to the term SPORÆ for their ſeeds. See that article, and HEDWIG.

SPORLING'S ISLAND, in *Geography*, a ſmall iſland near the coaſt of New Zealand, a little to the N.E. of Gable End Foreland.

SPORLIVOI, Nos, a cape of Ruſſia, on the S. coaſt of Nova Zembla. N. lat. 70° 30′. E. long. 60° 34′.

SPOROBOLUS, in *Botany*, from *σπορα*, *ſeed*, and *βαλλω*, *to throw*, becauſe, as we preſume, of the round deciduous ſeed.—Brown Prodr. Nov. Holl. v. 1. 169.—Claſs and order, *Triandria Digynia.* Nat. Ord. *Gramina.*

This genus of graſſes is ſeparated by Mr. Brown from *Agroſtis*, by the following characters.

Calyx of two unequal unarmed valves, containing a ſingle flower; the outer valve ſmalleſt. Corolla of two rather acute valves, without awns, ſeſſile, longer than the calyx. Nectary of two ſcales. Stigmas villous. Seed obovate, tumid, naked, deciduous.

The ſpecies are found between the tropics, ſcarcely beyond the latitude of 35°. Some have only two *ſtamens.* The *flowers* are panicled. Sheaths of the *leaves* bearded, with hardly any membranous *ſtipula.* They are akin to *Agroſtis*, eſpecially to *A. virginica.* *A. diandra* of Linnæus is a *Sporobolus*, as well as *A. indica.* Beſides the latter, two new ſpecies have been obſerved by Mr. Brown in New Holland, *S. elongatus* and *pulchellus.*

SPOROW, in *Geography*, a town of Lithuania, in the palatinate of Brzeſc, ſeated on a lake to which it gives name; 28 miles W. of Pinſk.

SPORTS, in the *Cuſtoms* of Flanders, were in great vogue through Flanders and the Low Countries ſome centuries ago. Every city had a ſolemnity of this kind peculiar to itſelf: thus Bruges had that called the *Foreſter;* Valenciennes, the *Prince of Pleaſantry*, and the *Prince of the Horſe-Comb;* Cambray, the *King of Ribaldry;* and Bouchain, the *Provoſt of Sots.* Liſle, one of the richeſt towns in Flanders, was not behind hand with its neighbours in celebrating ſports, by the magnificence and diverſions of which to draw together a vaſt concourſe of people from all parts. One of the chief of theſe divertiſements was called the *King of the Spinet*, *Roy d'Epinette*, which was celebrated with great pomp and ſhow. See Hiſt. Acad. Inſcript. tom. iv. p. 452, ſeq.

SPORTULA, or SPORTELLA, in *Antiquity*, a dole, or largeſs, either of meat or money, given by princes, or great men, to the people or poor.

The ſportula was properly the pannier or baſket in which the meat was brought, or with which the poor went to beg it; thence the word was transferred to the meat itſelf, and thence to money ſometimes given in lieu of it. The baſket was ſuppoſed to contain a quantity of hot proviſions, of the value of 100 quadrantes, or $12\frac{1}{2}$ pence; and theſe baſkets were ranged in order in the hall, and diſtributed oſtentatiouſly to the hungry or ſervile crowd, which waited at the door. This indelicate cuſtom is very frequently mentioned in the epigrams of Martial, and the ſatires of Juvenal. (See likewiſe Suetonius, in Claud. c. 21, in Neron. c. 16, in Domitian. c. 4. 7.) Theſe baſkets of proviſions were afterwards converted into large pieces of gold and ſilver coin, or plate, which were mutually given and accepted, even by perſons of the higheſt rank (ſee Symmach. epiſt. iv. 55. ix. 124. and Miſcell. p. 256.) on ſolemn occaſions, of conſulſhips, marriages, &c.

Sportula was alſo frequently uſed in oppoſition to *recta cœna*, a formal or plentiful meal; as in Martial.—"Promiſſa eſt nobis ſportula, recta data."

St. Cyprian gives the denomination *ſportulantes fratres*, to ſuch clergymen as then received gifts, or gratuities, for their maintenance.

SPOT, in *Ornithology*, the name of a particular ſpecies of pigeon, called by Moore the *columba maculata.* It is of the ſize of a ſmall common pigeon, and was brought over to England from Holland. This ſpecies has always a ſpot upon its head, juſt above its beak, from whence it has its name. The feathers of the tail are always of the ſame colour with this ſpot, and the reſt of the body is all white. The ſpot and tail are black in ſome, red in others, and yellow in others. They look very beautiful when they ſpread their tails and fly, and are a diſtinct ſpecies, as they always produce young ones of their own marks.

SPOTICO, in *Geography*, an iſland in the Grecian Archipelago, of an irregular form, about four miles long, and from one to two broad; 6 miles W.S.W. of Paros. N. lat. 36° 59′. E. long. 25° 12′.

SPOTS, in *Aſtronomy*, dark places obſerved on the diſks, or faces, of the ſun, moon, and planets.

The ſpots in the ſun are only viſible through a teleſcope: ſome diſtinguiſh them into maculæ, or dark ſpots; and faculæ, or bright ſpots; but there ſeems but little foundation for any ſuch diviſion.

The ſolar ſpots have not been long obſerved. They were firſt diſcovered by Galileo, in the year 1610, ſoon after he had finiſhed his teleſcope.

In oppoſition to the received opinion of the unalterable ſtate of the heavens, he maintained, that theſe ſpots conſiſted of a kind of matter that admitted of very great and ſudden alterations; that they adhered to the ſun, which carried them round an axis of his globe in about a month; which axis he firſt ſuppoſed to be perpendicular to the plane of the earth's annual orbit, becauſe the courſe of the ſpots appeared on the ſun's diſk as ſtraight lines parallel to that plane; which then happened through a particular direction of the floating motions of the ſpots upon the ſun's ſurface, as he ſoon inferred from the viſible alterations in their ſhapes and ſituations to one another, when ſeveral of them appeared together: and thence he concluded, that the general courſe of the ſpots was frequently varied a little, in like manner as, to a perſon viewing the earth from a great diſtance, the clouds would appear to move parallel to one another, and to the equator, with the uniform velocity of the earth's diurnal revolution, unleſs diſturbed a little from that regular courſe by their floating in the atmoſphere. At firſt he took the apparent motion of the ſun's to be, as we have ſtated, rectilinear and parallel to the ecliptic; but in conſequence of a ſubſequent obſervation of the entire tranſit of a large ſpot, and of marking its place at noon, day after day, upon a circular paper anſwering to the ſun's diſk, he found its courſe was a little incurvated; and thence he concluded, that the ſun's axis was a little inclined to the plane of the ecliptic.

Since Galileo's time, the ſubject of the ſun's ſpots has engaged the attention of ſeveral aſtronomical obſervers. The poſition of the ſun's axis, and the periodical time of his motion round it, have been more exactly determined, the knowledge of which depended upon the obſervation of theſe ſpots. In the year 1639, Scheiner publiſhed his "Roſa Urſina," containing near 2000 obſervations of ſolar ſpots for 20 years; in which time he frequently ſaw above 50 at once: but for 20 years after, betwixt 1650 and 1670, ſcarcely any appeared. He found that many of his ſpots ſcarcely exceeded 25 days in making an apparent revolution from a given place on the diſk to the ſame again, that others took up 27 days, and ſome others near 28. Scheiner and Caſſini the ſon have alſo obſerved, that the periodical times of the nearer ſpots to the equator are ſhorter than thoſe of the remoter; and Caſſini the father obſerved the like property in Jupiter's ſpots. Theſe irregularities create great difficulties in determining the time of the ſun's exact revolution about his axis. Caſſini the father, however, by comparing many diſtant obſervations together, found a common meaſure of many ſuch intervals of time to be $27^d\ 12^h\ 20^m$ very nearly. Hence it has been concluded, that the periodical time of the ſun's revolution to a fixed ſtar is $25^d\ 15^h\ 16^m$.

All ſpots conſiſt of a black part in the middle, of ſome irregular figure, encompaſſed with a nebulous border of a colour leſs dark; and it often happens, after a gradual decay and diſappearing of the black part, that its place ſeems brighter than the reſt of the ſun, and continues ſo for two or three days. Theſe brighter ſpots are called *faculæ;* which ſee.

The ſun's ſpots are very changeable as to number, form, &c. and are ſometimes in a multitude, and ſometimes none at all.

Some imagine they may become ſo numerous, as to hide the whole face of the ſun, at leaſt the greateſt part of it; and to this aſcribe what Plutarch tells us, *viz.* that in the firſt year of the reign of Auguſtus, the ſun's light was ſo faint and obſcure, that one might look ſteadily at it with the naked eye.

To which Kepler adds, that in 1547 the ſun appeared reddiſh, as when viewed through a thick miſt; and hence conjectures, that the ſpots in the ſun are a kind of dark ſmoke, or clouds, floating on the ſurface of it.

Others will have them ſtars, or planets, tranſiting the body of the ſun; but it is much more probable they are opaque bodies, in manner of cruſts, formed like the ſcums on the ſurface of liquors.

Dr. Derham, from a variety of particulars which he has recited, relating to the ſolar ſpots, (ſee Phil. Tranſ. abr. vol. iv. p. 235, &c.) and their congruity to what we obſerve in our own globe, infers, that they are cauſed by the eruption of ſome new volcano therein, which, at firſt, pouring out a prodigious quantity of ſmoke, and other opaque matter, cauſeth the ſpots: and as that fuliginous matter decays and ſpends itſelf, and the volcano at laſt becomes more torrid and flaming, ſo the ſpots decay and become umbræ, and at laſt faculæ; which faculæ he ſuppoſes to be no other than more flaming lighter parts than any other parts of the ſun.

Dr. Franklin (in his Exper. and Obſerv. p. 266.) ſuggeſts a conjecture, that the parts of the ſun's ſulphur, ſeparated by fire, riſe into the atmoſphere, and there being freed from the immediate action of the fire, they collect into cloudy maſſes, and growing, by degrees, too heavy to be longer ſupported, they deſcend to the ſun, and are burnt over again. Hence, he ſays, the ſpots appearing on his face, which are obſerved to diminiſh daily in ſize, their conſuming edges being of particular brightneſs. For other ſolutions of theſe phenomena, by Wilſon, Lalande, Herſchel, &c., ſee MACULÆ and SUN.

The lunar ſpots are fixed; and aſtronomers reckon about forty-eight of them on the moon's face, to each of which they have given names. The twenty-firſt is one of the moſt conſiderable, and is called *Tycho*. See *Nature*, &c. *of the* MOON.

SPOTS, *Circular*, in *Electricity*. See CIRCULAR *Spots* and COLOURS.

SPOTS, *Planetary*. Aſtronomers find that the planets are not without their ſpots. Jupiter, Mars, and Venus, when viewed through a teleſcope, ſhew ſeveral very remarkable ones: and it is by the motion of theſe ſpots, that we conclude the rotation of the planets round their axes, in the ſame manner as that of the ſun is deduced from the motion of his maculæ. See each planet in its proper place.

SPOTS, *Lucid, in the Heavens*, are little whitiſh ſpots, of which there are ſeveral, that appear magnified, and more luminous when ſeen through teleſcopes; and yet without any ſtars in them. One of theſe is in Andromeda's girdle, and was firſt obſerved, A.D. 1712, by Simon Marius: it has ſome whitiſh rays near its middle, is liable to ſeveral changes, and is ſometimes inviſible. Another is near the ecliptic, between the head and bow of Sagittarius; it is ſmall, but very luminous. A third is in the back of the Centaur, which is too far ſouth to be ſeen in Britain. A fourth, of a ſmaller ſize, is before Antinous's right foot, having a ſtar in it, which makes it appear more bright. A fifth is in the conſtellation of Hercules, between the ſtars ζ and η, which ſpot, though ſmall, is viſible by the bare eye, if the ſky be clear and the moon abſent.

SPOTSWOOD, in *Geography*, a ſmall town of Middleſex county, New Jerſey, near the weſt ſide of South river, which diſcharges itſelf into the Rariton, in a ſouth-eaſt direction. It is well ſituated for extenſive manufactories; 9 miles S.E. of Brunſwick.

SPOTSYLVANIA, a county of the American ſtate of Virginia, bounded north by Stafford, and eaſt by Caroline county. It is hilly, and well watered by branches of the Mattapony and Rappahannock rivers. It contains 13,296 inhabitants, of whom 7135 are ſlaves. At the court-houſe is a poſt-office; 78 miles from Waſhington.

SPOTTED Island, an iſland in the North Atlantic ocean, on the eaſt coaſt of Labrador. N. lat. 53° 30′. W. long. 55° 20′.

SPOTTING, Finger, known alſo by the name of *Brocading*, in the *Manufacture of fanciful ornamented Cloths*, is a very beautiful, though rather expenſive, mode of interweaving flowers, either of the ſame or different colours, with various kinds of grounds. Of its primary origin we are totally unacquainted, as we find it practiſed alike, and with little variation of apparent effect, in the ſilks of Europe and the muſlins of India. It is probable that the whole range of fanciful cloths, with which we are acquainted, are originally Aſiatic; and that the knowledge of them has gradually reached Europe, at various times, and through various channels. In ſpots wrought with the ſhuttle, the flowers being at intervals, and the woof paſſed acroſs the whole fabric, what paſſes between the flowers, and is not interwoven with the fabric, muſt be cut away, when the cloth is taken from the loom, and before it undergoes the ſucceeding proceſſes of bleaching and dreſſing. Some ſpecimens of brocaded muſlins have been occaſionally brought from India, which are entirely effected by a continued and patient exerciſe of manual labour truly aſtoniſhing. The low price of labour paid to the natives of that country may produce theſe figured muſlins, at prices acceſſible to the opulent natives, and to the more wealthy claſſes of the European ſettlers. In this country, even at the moſt reduced prices, capable of affording to the operative the moſt penurious and ſcanty ſubſiſtence, they could not be afforded under four or five guineas *per* yard; a ſum immenſely beyond what could be expected for a commodity ſo flimſy and periſhable as a muſlin dreſs.

In finger-flowers, or brocaded muſlins, the draught through the heddles is generally ſucceſſive from the back to the front, as in moſt kinds of fanciful weaving. The treddles are moved by the feet, as in the common proceſſes, for forming the plain ground or fabric of the work. For the flowers or raiſed part, thoſe leaves which require to be raiſed are moſt commonly pulled by cords above the weaver's head, as in the diaper and patent draw-loom; and, like them, ſecured by a knot upon the cord, being fixed in a notch in the board. The weaver then proceeds to paſs the ſubſtance, which is to form the flowers, through the warp; each end being ſeparated from, and independent of, all the others. In this he is generally aſſiſted by a boy, who ſits at the loom along with him, and who manages one ſide of the web, while the weaver is employed on the other. From this tedious and laborious operation being done entirely by the fore-finger, the appellation *finger-flower* is derived. Our limits will not allow of a very lengthened detail, nor would it be of any eſſential ſervice; for, from the cauſes already aſſigned, there is no probability of its ever becoming an article of extenſive manufacture in this country.

SPOTTISWOODE, John, in *Biography*, a prelate and eccleſiaſtical hiſtorian of Scotland, deſcended from an ancient family in that country, was born in 1565. His father, who was a miniſter of Calder, ſent him to the univerſity of Glaſgow to be educated for the church; and his proficiency in his ſtudies was ſuch, that at the age of eighteen he was thought to be qualified to be his father's ſucceſſor. When Lodowick, duke of Lenox, was ſent, in 1601, on an embaſſy to France, for the purpoſe of confirming the ancient amity between the two countries, Spottiſwoode, with the hope of conciliating the two nations, accompanied him as chaplain, and returned with him to England. His reputation was at that time ſo high, that, on the acceſſion of king James to the crown of England in 1603, he was one of the perſons appointed to attend his majeſty to his newly acquired kingdom; and in the ſame year he was promoted to the archbiſhopric of Glaſgow, and nominated a privy-counſellor for Scotland. It was the favourite object of James to aſſimilate as much as poſſible the church of Scotland to the model of that of England; and archbiſhop Spottiſwoode was very eager in promoting this intention, and is ſaid to have made fifty journies to London on that account. Having held the ſee of Glaſgow eleven years, he was tranſlated, in 1615, to that of St. Andrews, the metropolitan of Scotland; and he preſided at various aſſemblies for the reſtoration of the epiſcopal form of government. He continued in high favour with king James during his whole reign; and Charles I., after his acceſſion, was crowned by him in the abbey church of Holyrood Houſe. In 1635 he was appointed chancellor of Scotland. When the civil commotions broke out in that country in 1639, the archbiſhop withdrew to England, where he died, and was interred in Weſtminſter Abbey. He was author of "A Hiſtory of the Church of Scotland," beginning with the year 203, and continued to the end of the reign of James VI., which was publiſhed in London in 1655. This work was undertaken at the command of king James, who, when Spottiſwoode told him ſome paſſages might bear hard on the memory of his mother, ſaid, "Write the truth, and ſpare not." Spottiſwoode was author of "Refutatio Libelli de Regimine Eccleſiæ Scoticanæ," written in defence of the eccleſiaſtical eſtabliſhment of Scotland.

SPOULT, in *Rural Economy*, a word ſignifying brittle, as applied to wood, &c.

SPOUT, the name of a trunk for conveying water from off the roofs of buildings, which ſhould always be attached to thoſe of the farm-kind. Spouts on ſuch buildings are not only uſeful for freeing them of water, but in collecting it for the purpoſe of the live-ſtock, &c.

Spout, or *Water-ſpout*, in *Natural Hiſtory*, an extraordinary meteor, or appearance, at ſea, and ſometimes on land, very dangerous to ſhips, &c. ofteneſt obſerved in hot, dry weather; and called by the Latins *typho*, and *ſipho*; by the French, *trompe*, &c.

Its firſt appearance is in form of a deep cloud, the upper part of which is white, and the lower black. From the lower part of this cloud there hangs, or rather falls down, what we properly call the ſpout, in manner of a conical tube, biggeſt at top. Under this tube is always a great boiling and flying up of the water of the ſea, as in a jet d'eau. For ſome yards above the ſurface of the ſea, the water ſtands as a column, or pillar; from the extremity of which it ſpreads, and goes off, as in a kind of ſmoke. Frequently the cone deſcends ſo low, as to touch the middle of this column, and continue for ſome time contiguous to it; though ſometimes it only points to it, at ſome diſtance, either in a perpendicular, or in an oblique line.

Frequently it is ſcarcely diſtinguiſhable, whether the cone or the column appear the firſt, both appearing all of a ſudden againſt each other. But ſometimes the water boils up from the ſea to a great height, without any appearance of a ſpout pointing to it, either perpendicularly or obliquely. Indeed, generally, the boiling or flying up of the water has the priority, this always preceding its being formed into a column. Generally the cone does not appear hollow till towards the end, when the ſea-water is violently thrown up along its middle, as ſmoke up a chimney: ſoon after this the ſpout, or canal, breaks and diſappears; the boiling up of the water, and even the pillar, continuing to the laſt, and for ſome time afterwards; ſometimes till the ſpout form itſelf again, and appear anew; which it ſometimes does ſeveral times in a quarter of an hour. See a deſcription of ſeveral water-ſpouts by Mr. Gordon, and by Dr. Stuart, in Phil. Tranſ Abr. vol. iv. p. 103, &c.

M. de la Pryme, from a near obſervation of two or three ſpouts in Yorkſhire, deſcribed in the Philoſophical Tranſactions, N° 281, or Abr. vol. iv. p. 106, concludes, that the water-ſpout is nothing but a gyration of clouds, by contrary winds meeting in a point, or centre; and there, where the greateſt condenſation and gravitation are, falling down into a pipe, or great tube, ſomewhat like Archimedes's ſpiral ſcrew; and, in its working and whirling motion, abſorbing and raiſing the water, in the ſame manner as the ſpiral ſcrew does; and thus deſtroying ſhips, &c.

Thus, June the 21ſt, he obſerved the clouds mightily agitated above, and driven together; upon which they became very black, and were hurried round; whence proceeded a moſt audible whirling noiſe, like that ordinarily heard in a mill. Soon after there iſſued a long tube or ſpout from the centre of the congregated clouds, in which he obſerved a ſpiral motion, like that of a ſcrew, by which the water was raiſed up.

Again, Auguſt 15, 1687, the wind blowing at the ſame time out of the ſeveral quarters, created a great vortex and whirling among the clouds; the centre of which every now and then dropped down, in ſhape of a long, thin, black pipe, in which he could diſtinctly behold a motion like that of a ſcrew, continually drawing upwards, and ſcrewing up, as it were, wherever it touched. In its progreſs it moved ſlowly over a grove of trees, which bent under it like wands, in a circular motion. Proceeding, it tore off the thatch from a barn, bent an huge oak-tree, broke one of its greateſt branches, and threw it to a great diſtance. He adds, that whereas it is commonly ſaid, the water works and riſes in a column, before the tube comes to touch it; this is, doubtleſs, a miſtake, owing to the fineneſs and tranſparency of the tubes, which do moſt certainly touch the ſurface of the ſea, before any conſiderable motion can be raiſed in it; but which do not become opaque and viſible, till after they have imbibed a conſiderable quantity of water.

The diſſolution of water-ſpouts he aſcribes to the great quantity of water they have glutted; which, by its weight, impeding their motion, on which their force, and even exiſtence, depends, they break, and let go their contents; which generally prove fatal to whatever is found underneath.

A notable inſtance of this kind we have in the Philoſophical Tranſactions, N° 363, or Abr. vol. iv. p. 108, related by Dr. Richardſon. A ſpout, in 1718, breaking on Emmotmoor, near Coln, in Lancaſhire, the country was immediately overflowed; a brook, in a few minutes, roſe ſix feet perpendicularly high; and the ground on which the ſpout fell, which was ſixty-ſix feet over, was torn up to the very rock, which was no leſs than ſeven feet deep; and a deep gulf was made for above half a mile; the earth being raiſed on either ſide in vaſt heaps. See a deſcription and figure of a water-ſpout, with an attempt to account for it, in Franklin's Exp. and Obſ. p. 226, &c.

Signior Beccaria has taken pains to ſhew that water-ſpouts have an electrical origin. To make this more evident, he firſt deſcribes the circumſtances attending their appearance, which are the following.

They generally appear in calm weather. The ſea ſeems to boil, and ſend up a ſmoke under them, riſing in a hill towards the ſpout. At the ſame time, perſons who have been near them have heard a rumbling noiſe. The form of a water-ſpout is that of a ſpeaking-trumpet, the wider end being in the clouds, and the narrower end towards the ſea. The ſize is various, even in the ſame ſpout. The colour is ſometimes inclining to white, and ſometimes to black. The poſition is ſometimes perpendicular to the ſea, ſometimes oblique; and ſometimes the ſpout itſelf is in the form of a curve. Their continuance is very various, ſome diſappearing as ſoon as formed, and ſome continuing a conſiderable time. One that he had heard of continued a whole hour. But they often vaniſh, and preſently appear again in the ſame place.

The very ſame things that water-ſpouts are at ſea, are ſome kinds of whirlwinds and hurricanes by land. They have been known to tear up trees, to throw down buildings, make caverns in the earth; and, in all theſe caſes, to ſcatter earth, bricks, ſtones, timber, &c. to a great diſtance, in every direction. Great quantities of water have been left, or raiſed by them, ſo as to make a kind of deluge; and they have always been attended with a prodigious rumbling noiſe.

That theſe phenomena depend upon electricity, cannot but appear very probable from the nature of ſeveral of them; but the conjecture is made more probable from the following additional circumſtances. They generally appear in months peculiarly ſubject to thunder-ſtorms, and are commonly preceded, accompanied, or followed, by lightning, rain, or hail; the previous ſtate of the air being ſimilar. Whitiſh or yellowiſh flaſhes of light have ſometimes been ſeen moving with prodigious ſwiftneſs about them. And, laſtly, the manner in which they terminate, exactly reſembles what might be expected from the prolongation of one of the uniform protuberances of electrified clouds, mentioned before, towards the ſea; the water and the cloud mutually attracting one another; for they ſuddenly contract themſelves, and diſperſe almoſt at once; the cloud riſing, and the water of the ſea under it falling to its level. But the moſt remarkable circumſtance, and the moſt favourable to the ſuppoſition of their depending upon electricity, is, that they have been diſperſed by preſenting to them ſharp-pointed knives or ſwords. This, at leaſt, is the conſtant practice of mariners, in many parts of the world where theſe water-ſpouts abound; and he was aſſured by ſeveral of them, that the method has often been undoubtedly effectual.

The analogy between the phenomena of water-ſpouts and electricity, he ſays, may be made viſible, by hanging a drop of water to a wire communicating with the prime conductor, and placing a veſſel of water under it. In theſe circumſtances, the drop aſſumes all the various appearances of a water-ſpout, both in its riſe, form, and manner of diſappearing. Nothing is wanting but the ſmoke, which may require a great force of electricity to become viſible.

Mr. Wilcke alſo conſiders the water-ſpout as a kind of great electrical cone, raiſed between the cloud ſtrongly electrified, and the ſea or the earth; and he relates a very remarkable appearance, which occurred to himſelf, and which ſtrongly confirms his ſuppoſition. On the 20th of July, 1758, at three o'clock in the afternoon, he obſerved a great quantity of duſt riſing from the ground, and covering a field and part of the town in which he then was. There was no wind, and the duſt moved gently towards the eaſt, where appeared a great black cloud, which, when it was near its zenith, electrified his apparatus poſitively, and to as great a degree as ever he had obſerved it to be done by natural electricity. This cloud paſſed its zenith, and went gradually towards the weſt, the duſt then following it, and continuing to riſe higher and higher, till it compoſed a thick pillar, in the form of a ſugar-loaf, and at length ſeemed to be in contact with the cloud. At ſome diſtance from this there came, in the ſame path, another great cloud, together with a long ſtream of ſmaller clouds, moving faſter than the preceding. Theſe clouds electrified his apparatus negatively, and when they came near the poſitive cloud, a flaſh of lightning was ſeen to dart through the cloud of duſt, the poſitive cloud, the large negative cloud, and, as far as the eye could diſtinguiſh, the whole train of ſmaller negative clouds which followed it. Upon this the negative clouds ſpread very much, and diſſolved into rain, and the air was preſently clear of all the duſt. The whole appearance laſted not above half an hour. See Prieſtley's Electr. vol. i. p. 438, &c.

This theory of water-ſpouts has been farther confirmed by the account which Mr. Forſter gives of one of them in his Voyage round the World, vol. i. p. 191, &c. On the coaſt of New Zealand he had an opportunity of obſerving ſeveral, one of which he has particularly deſcribed. The water, he ſays, in a ſpace of fifty or ſixty fathoms, moved towards the centre, and there riſing into vapour, by the force of the whirling motion, aſcended in a ſpiral form towards the clouds. Directly over the whirlpool, or agitated ſpot in the ſea, a cloud gradually tapered into a long ſlender tube, which ſeemed to deſcend to meet the riſing ſpiral, and ſoon united with it into a ſtraight column of a cylindrical form. The water was hurled upwards with the greateſt violence in a ſpiral, and appeared to leave a hollow ſpace in the centre, ſo that the water ſeemed to form a hollow tube, inſtead of a ſolid column; and that this was the caſe, was rendered ſtill more probable by the colour, which was exactly like that of any hollow glaſs tube. After ſome time, this laſt column was incurvated, and broke like the others; and the appearance of a flaſh of lightning which attended its disjunction, as well as the hail-ſtones which fell at the time, ſeemed plainly to indicate that water-ſpouts either owe their formation to the electric matter, or at leaſt that they have ſome connection with it.

Mr. Cavallo (Elem. of Phil. vol. ii.) has detailed the following facts, as the moſt remarkable, relative to water-ſpouts.

Two or three, or more, water-ſpouts are frequently ſeen within the ſpace of a few miles, and they are moſtly ſeen at ſea.

Their ſize is various, not exceeding, however, a few feet in diameter; and the ſame water-ſpout ſometimes increaſes and decreaſes alternately; it alſo appears, diſappears, and re-appears, in the ſame place.

The water-ſpout ſometimes proceeds a little way from a cloud, or a little way from the ſea; and often thoſe two ſhort and oppoſite ſpouts are not only directed towards each other, but they are extended, and meet each other.

When it proceeds from the ſea, the water about the place appears to be much agitated, and riſes a ſhort way in the form of a jet, or ſpray, or ſteam, in the middle of which a thick, well defined, and generally opaque body of water riſes, and proceeds to a conſiderable height into the atmoſphere, where it is diſſipated into a vapour, or it ſeems to form a cloud.

When it proceeds from a cloud, the clouds about the ſpot frequently appear much agitated, and an agitation of the water immediately under the ſpot is generally ſeen at the ſame time.

The water-ſpout is frequently ſeen to have a ſpiral or ſcrew-like motion, and ſometimes is attended with conſiderable noiſe.

Some of them ſtand in a perpendicular direction, others are inclined, and ſome water-ſpouts form a curve, or even an angle.

The water-ſpouts generally break about their middle, and the falling waters occaſion great damage, either to ſhips that have the misfortune of being under them, or to the adjoining land; for ſuch ſpouts are ſometimes formed on a lake or river, or on the ſea cloſe to the land.

Sometimes the water-ſpouts are ſeen where there is no appearance of whirlwind, or where the wind, at leaſt to a ſpectator at ſome diſtance, appears to blow regularly one way.

The oblique ſpouts almoſt always point from the wind; for inſtance, when the wind is N.E. the ſpout will point to the S.W.

The water-ſpout has been attributed principally, if not entirely, to the meeting of different winds. In that caſe, the air in its rotation acquires a centrifugal motion; whence it endeavours to recede from the axis of the whirl, in conſequence of which a vacuum, or, at leaſt, a conſiderable rarefaction of air, takes place about the axis; and, when the whirl takes place at ſea, or upon water, the water riſes into that rarefied place, for the ſame reaſon which cauſes it to aſcend into an exhauſted tube, and forms the water-ſpout or pillar of water in the air: nevertheleſs it is obſerved by Mr. Cavallo, that the various appearances of water-ſpouts do not ſeem to be quite reconcileable to the above-mentioned theory. Several ingenious perſons have conſidered the water-ſpout as an electrical phenomenon; having obſerved, that thunder-clouds and lightning have been frequently ſeen about the places where water-ſpouts appear, and likewiſe that by means of artificial electricity, a water-ſpout may in ſome meaſure be imitated. (See the preceding part of this article.) Mr. Cavallo, however, ſuggeſts, that the lightning and other electrical phenomena appear to be rather the neceſſary conſequence than the cauſe of the water-ſpout; it being well known that electricity is produced whenever water is reduced into vapour, or vapour is condenſed into water. A water-ſpout of the moſt complete form is repreſented in *Plate* XXIV. *Miſcellany*, *fig.* 8.

In Pliny's time, the ſeamen uſed to pour vinegar into the ſea, to aſſuage and lay the ſpout, when it approached them: our modern ſeamen think to keep it off, by making a noiſe with filing and ſcratching violently on the deck, or by diſcharging great guns to diſperſe it.

SPOUTING FOUNTAIN. See FOUNTAIN.

SPOUTY *Ground* or *Land*, in *Agriculture*. See SOIL, and SPRING-*Draining*.

SPRAGGE, *Sir* EDWARD, in *Biography*, a celebrated naval hero and commander, of whoſe early hiſtory nothing has been collected, but who deſerves a place in the annals of England, and whoſe ſervices will be ever remembered with graditude by his country. He is compared by Campbell to Alcibiades, who was equally able and eſteemed in the camp, in the court, and in the cloſet. "In every character which he aſſumed, he ſo far excelled as to ſeem born and deſigned for that alone. The ſame thing his contemporaries, his companions, thoſe who knew him, and the world too, perfectly well, affirm of ſir Edward Spragge, who with a fine perſon, and gentle temper, had as ſolid an underſtanding, and as bold a ſpirit, as any counſellor or captain of that age. With all theſe advantages, with the favour of the duke of York, with the merit of great ſervices which he rendered his country, and with the ſtill greater merit of dying glorioſly in his country's ſervice, which, indeed, procured his remains an interment in Weſtminſter Abbey, he was not honoured with a tomb; or any memorial, as far as treatment, however, and particularly the unmanageableneſs and imprudence of patients, who fatigue the joint in uſing it too ſoon and before the pain is over, may render a ſprain very bad even in ſubjects who are in other reſpects perfectly ſound. In this caſe, ſometimes the pain and ſwelling, after having undergone a greater or leſſer abatement, ſtill continue in a degree, ſo that a diſeaſe, which might have been cured in five or ſix weeks, laſts five or ſix months, and frequently a whole year. Sometimes the ſymptoms get worſe inſtead of becoming better. The pain and ſwelling occur in the higheſt degree, and ſuppuration itſelf, followed by caries of the bones, may follow, and even create a neceſſity for amputation in order to ſave the patient's life.

But ſymptoms of this violent nature are ſeldom remarked after ſprains, except in ſubjects who labour under ſome conſtitutional diſorder, which may extend its effects to the joints. The moſt common, and at the ſame time the moſt afflicting, is ſcrofula. In patients diſpoſed to this diſeaſe, ſprains often become the occaſional or exciting cauſe of white-ſwellings, which too frequently baffle all the efforts of the moſt ſkilful ſurgeons, and make amputation indiſpenſable.

The ſymptoms which characterize ſprains are eaſy of comprehenſion. An application of external violence, the nature and direction of which are always known; a more or leſs acute pain in the affected joint, without deformity, without any manifeſt alteration in the natural relations of the articular ſurfaces; a free power of motion immediately after the accident; and a ſudden ſwelling proportioned to the violence of the ſhock. Such are the circumſtances denoting a ſprain. A ſprain may readily be diſtinguiſhed from every other affection of the joints. Uninformed practitioners have been known, however, to miſtake its nature, and thence do conſiderable miſchief, by ill-judged attempts to remedy a ſeparation of bones, or to reduce a diſlocation which never exiſted. So groſs a miſtake may eaſily be avoided by the leaſt attention.

The prognoſis of ſprains differs according to the degree of the injury, the nature of the joint, and the particular conſtitution of the patient. A ſlight ſprain is a caſe of little importance, being generally cured in a few weeks, when properly treated, and when the patient, obedient to the advice of the ſurgeon, keeps the joint perfectly motionleſs, and avoids uſing the limb until the pain and ſwelling are entirely removed. A violent ſprain, occurring to a joint that is ſtrengthened by very ſtrong ligaments, like that of the ankle for example, is a ſevere caſe, which often laſts ſeveral months, and which, as we have already explained, may have afflicting conſequences, when it is badly treated, or the patient does not conform to the advice of his ſurgeon. Even a ſlight ſprain is always a ſevere accident in ſcrofulous ſubjects, becauſe it may become an exciting cauſe of a white-ſwelling, and produce a neceſſity for amputation.

The treatment of ſprains conſiſts in preventing the inflammatory ſwelling, diſperſing it when it has taken place, promoting the union of the torn ligaments, and re-eſtabliſhing the tone, force, and freedom of motion in the affected joint.

Experience has taught, that cold water is the beſt application which can be uſed for fulfilling the firſt indication. This diſcutient appeaſes the pain, and tends to prevent ſwelling and inflammation. Cold water is rendered more ſedative and efficacious, when a little of the liquor plumbi acetatis is added to it. Thus, when a ſurgeon is conſulted immediately after the accident, the part ſhould be immerſed in a pail of ſpring water, into which the liquid acetite of lead has been put in the proportion of a drachm to a pint. Some practitioners make the quantity greater; but, we believe, what is here mentioned is quite ſufficient. In order to derive all the advantage poſſible from the employment of cold water, the part ſhould remain immerſed ſeveral hours without interruption, and the water ſhould be changed as ſoon as it becomes warmed. Boyer does not approve, however, of uſing this application for women who have their menſes on them; or for patients whoſe lungs are weak, or who are ſubject to hæmoptyſis; or for any perſons who are in a great perſpiration. Perhaps, in ſuch inſtances, it may be as well to uſe a warm linſeed poultice.

After the part has been taken out of the water, it is to be covered with linen wet with the ſame application, and care muſt be taken frequently to wet the cloths anew, ſo that they may be as cold as poſſible, and the evaporation effectual.

When the ſprain is ſlight, diſcutients are commonly adequate to the prevention of the inflammatory ſwelling, and they may be continued till the caſe is quite well. But if the injury be too ſevere to yield to theſe means, or ſhould they not have been tried in the firſt inſtance, ſo that tenſion and ſwelling have already come on, recourſe muſt be had to the means proper for fulfilling the ſecond indication, that is to ſay, for diſperſing the pain and inflammatory ſwelling. The patient may be bled more or leſs copiouſly according to his age, ſtrength, conſtitution, and ſeverity of the accident. Low diet and abſolute reſt are to be directed, and topical emollient anodyne applications are to be made to the part affected; ſuch as linſeed poultices, and fomentations of white poppy-heads. When the pain is exceſſively ſevere, a ſmall quantity of laudanum, or of a watery ſolution of opium, may be mixed with the poultice.

The uſe of theſe local applications is to be continued as long as the pain and ſwelling exiſt; but as ſoon as they are removed, diſcutients muſt be employed; ſuch as camphorated ſpirit of wine, ſoap liniment, ammoniated oil, and many kinds of mineral waters.

During the whole treatment, and even a long while afterwards in ſevere caſes, the part affected muſt be kept ſtrictly at reſt. On one hand, moving the joint might keep up the irritation and inflammation; on the other, when the ſprain has been conſiderable and the ligaments lacerated, a firm union of them, and the return of the ſtrength which is eſſential to the perfect functions of the articulation, can only be obtained by long reſt.

When a ſprain happens to the ankle, as is moſt common, the patient ſhould not be ſuffered to walk before the pain and ſwelling are entirely removed. As there remains in the joint almoſt always a weakneſs, which ſubjects the patient to the ſame accident again, when he walks too quickly, or careleſsly, it is proper, with a view of obviating this inconvenience, to apply a moderately tight roller to the part, or to direct him to wear for ſome time a laced ſoft leather buſkin.

It frequently happens, after the cure of a ſprain, when the joint has recovered all its ſtrength and freedom of motion, that the ſurrounding cellular ſubſtance is puffy and œdematous, eſpecially in the evening, after the patient has been long in the erect poſition. The moſt efficacious means which can be uſed againſt this local infirmity, which may continue a long while, is the compreſſion of a bandage, or laced dog-ſkin ſtocking.

In other caſes, the ligaments, which have been violently diſtended and lacerated, become rigid, and the motion of the joint remains imperfect. Here fomentations, emollient baths, vapour baths, and oily liniments, are indicated.

Laſtly, when the ſtiffneſs of the joint reſiſts theſe means, the efficacy of hydro-ſulphurated waters may be tried.

In ſcrofulous ſubjects, ſprains may be followed by the moſt ſevere conſequences, as already related, and may become the exiſting cauſe of an inveterate diſeaſe of the joint. The conſideration of the treatment of the diſorder here alluded to, will be found in a future article of this publication. (See WHITE-SWELLING.) Boyer Traité des Maladiès Chirurgicales, tom. iv. ch. 1.

SPRAIN, among horſes, and other ſorts of live-ſtock, a violent extenſion of ſome tendinous part, by which ſudden lameneſs is not unfrequently produced. It is moſtly capable of being removed by ſaturnine, ſpirituous, or acid waſhes, with proper elaſtic bandages, and a little reſt. It often happens in the legs of horſes, and ſome other animals.

SPRAIN, in *Agriculture*, a term applied to the ſowing of ſeeds by hand, ſignifying to throw them into their places with a ſingle motion of the hand, at a certain diſtance from one another. It is particularly applied to beans, and ſome other kinds of feed. Spraining in crops is not unfrequently practiſed in particular places where labour is cheap.

SPRAINTS, among *Sportſmen*, a term uſed for the dung of the otter.

SPRANGENBERG, in *Geography*, a town of the principality of Heſſe Caſſel; 6 miles S. of Lichtenau.

SPRANGER, BARTHOLOMEW, in *Biography*, was the ſon of Joachim Spranger, a merchant of eminence at Antwerp, and was born there in 1546. As he exhibited an inclination for painting, he was placed as a diſciple with John Madyn, a painter of ſome reputation at Haerlem, and afterwards with Francis Moſtaert. He then went to Italy through France, and reſided ſome years at Parma as a ſtudent, under Bernardino Gatti, who had been a diſciple of Correggio. He thence went to Rome, where the cardinal Farneſe favoured him with his patronage, and engaged him to paint, in the Villa Caprarola, ſeveral landſcapes in freſco. By the cardinal he was introduced to the pope, Pius V., who appointed him his painter, and gave him apartments in the Palazzo Belvidere. His firſt work for his holineſs was a picture of the Laſt Judgment, a compoſition of five hundred figures, painted upon a copper-plate ſix feet high. This picture is ſaid to have taken him three years to complete, and to have been, of courſe, finiſhed with great care; and in conſequence of its being highly eſteemed by the pope, it was placed upon his tomb, after his deceaſe. The ſame kind patron commiſſioned him to paint twelve pictures of the paſſion of our Saviour, but did not live to witneſs their completion.

The renown of Spranger now reached the court of Vienna, to which he was invited by the emperor Maximilian II. in 1575, and appointed his principal painter. On that emperor's death in the following year, his ſucceſſor, Rodolphus II., continued to ſhew the ſame favour to Spranger, and engaged him in ſeveral works of importance both at Vienna and at Prague; reſpecting him highly, not only for his abilities as a painter, but alſo for his literary acquirements, and other accompliſhments. In 1588 he was ennobled by his imperial majeſty, who honoured him by placing round his neck, with his own hands, a chain of gold, with a medal attached to it. Spranger died at Prague, in 1623, aged 77.

The ſtyle of this painter is that which was built upon the defects of Michael Angelo, or rather in the perverſion of his ſtyle, by a crude and indigeſted adoption of its moſt prominent character, without the judicious taſte and feeling in which it originated. It was conſequently extravagant and bombaſtic, preſenting inflated muſcles, and knobby excreſcences for bones, redeemed only in ſome eyes by a lively fancy, an agreeable facility of execution, and a pleaſing colour.

SPRAT, THOMAS, biſhop of Rocheſter, a writer of conſiderable eminence in the 17th century, was born in 1636 at Tallaton, in Devonſhire, where his father was a clergyman. He received his academical education at Wadham college, Oxford, of which Dr. Wilkins was then warden, under whom he acquired a proficiency in mathematical knowledge. In 1657 he was elected a fellow of his college; and on the death of Oliver Cromwell, he gave a ſpecimen of his poetical talents in an "Ode to the happy Memory of the late Lord Protector," addreſſed to Dr. Wilkins. This ode was followed by one on the "Plague of Athens," which, as well as the former, afforded proof of a warmth and readineſs of conception. At the Reſtoration, like many others, he made a ſhort turn, and atoned for his former delinquency by zealous loyalty, and was made chaplain to the duke of Buckingham, who was his zealous friend and patron. He was choſen a member of the Royal Society, which was then in its infancy, and which had originated from the meetings of the ſcientific men held at the lodgings of Dr. Wilkins, in Wadham college. In 1667 Sprat publiſhed the hiſtory of this ſociety, and its foundation; and obtained a high reputation for the elegance of the ſtyle and ſentiment exhibited in the work. He had publiſhed, two years previouſly to this, "Obſervations on Sorbiere's Voyage to England," which were well received, and conſidered as a ſeaſonable caſtigation of a ſuperficial foreigner who had vilified the country. In 1668 he was editor of Cowley's Latin poems, to which he prefixed a life of the author, in the ſame language. This he afterwards enlarged in Engliſh, and annexed to the Engliſh works of that poet. He had now attained a degree of reputation, which, joined to his talents for converſation and ſociety, cauſed him to be rapidly advanced in the career of preferment. He was ſucceſſively made a prebendary of Weſtminſter, rector of St. Margaret's, canon of Windſor, dean of Weſtminſter, and finally, in 1684, was raiſed to the epiſcopal bench as biſhop of Rocheſter. This laſt preferment was conſidered as a reward for the ſervice of drawing up, at the command of the king, an account of the Rye-houſe plot. This was firſt printed in 1685, and was reprinted in the following year, after James II. had ſucceeded to the throne. The manner in which he had executed this taſk rendered it expedient for him to publiſh an apology, after the Revolution. He had reflected on the characters of thoſe, whoſe names have been long ranked among the martyrs to liberty. Of lord Ruſſell, Sprat obſerves, "that he was carried away into this traiterous conſpiracy from a vain air of popularity, and a wild ſuſpicion of loſing a large eſtate by an imaginary return of popery." His favour under the new reign was manifeſted by his appointment to the place of clerk of the cloſet to the king, and his nomination as one of the commiſſioners for eccleſiaſtical affairs. At the revolution he ſubmitted to the new government, and was allowed to remain unmoleſted in his ſee. His principles, however, being well known, he was involved, in 1692, with others, in an information laid before the privy council, of a pretended conſpiracy for reſtoring king James. He detected the infamy of the informers, and effectually cleared himſelf from the charge; but he was ſo much affected by the danger he had undergone, that he ever after commemorated his deliverance by annual thankſgiving. He paſſed the reſt of his life in the practice of profeſſional duties and virtues, by which he engaged the eſteem and affection ſection of thoſe with whom he was connected, and died in 1713, in the 79th year of his age. Beſides the works already mentioned, he publiſhed a relation of his examination before the privy council, two letters to lord Dorſet, and a volume of ſermons. Biog. Brit.

Sprat, in *Ichthyology*, a ſpecies of the clupea, with the lower jaw the longeſt, and the belly very acute, and the dorſal fin conſiſting of thirteen rays. See Clupea.

The ſprat, or *clupea ſprattus* of Linnæus, has generally, but erroneouſly, been ſuppoſed a herring not grown to its full ſize. Its uſual length is about four or five inches, and the body much deeper than that of a young herring of equal length; the back fin is placed more remote from the noſe than that of the herring: but one great diſtinction between this fiſh, the herring, and the pilchard, is the belly; that of the two firſt being quite ſmooth, that of the laſt very ſtrongly ſerrated; and another is, that the herring has fifty-ſix vertebræ, this only forty-eight. Beſides, ſprats viſit our coaſts, and continue with us in large ſhoals, when the others, in general, have retired to the great northern deeps. They come into the river Thames, below bridge, in the beginning of November, and leave it in March, and are, during their ſeaſon, a great relief to the poor of the capital. At Graveſend and at Yarmouth they are cured like red herrings: they are ſometimes pickled, and are little inferior in flavour to the anchovy, but the bones will not diſſolve like thoſe of the latter. Pennant.

SPRATT, in *Agriculture*, a name applied in ſome places to a plant, which is found to riſe in great abundance, in a ſpontaneous manner, in moſt watery ſituations of the more ſound boggy kind. It is ſtated in a paper in the third volume of the "Tranſactions of the Highland Society of Scotland," that though it abounds much in that part of the kingdom, the proper culture of it is by no means well underſtood. It ſhould, it is ſaid, be ſuitably manured for with compoſt manure, once in three years; or watering ſometimes anſwers the ſame intention very well, in caſes where it is grown for hay; the land being preſerved from cattle, or other ſorts of ſtock, from the month of March; and the plants cut for hay in July at the lateſt. The feeding ſtalks are alſo ſtated to have been mown, after the cattle in paſturage, to benefit.

The ſpring froſts occaſionally, however, deſtroy ſome inches of the tops of the plants.

Sheep may ſafely eat it, without danger of rotting them; and it raiſes young cattle, it is ſaid, to a great ſize of bone. But that when ſuffered to run up to ſeed, it is not palatable; though cattle not unfrequently get it for hay in that ſtate. Where manure is uſed, and it is cut in the ſap, it conſtitutes, it is obſerved, a moſt excellent and abundant kind of hay for black cattle. In this management, it has been ſeen ready for the ſcythe as ſoon as rye-graſs; and one of the beſt ſamples of meadow hay ſeen in the above part of the country was cut in the year 1804, and conſiſted of ſpratt and common poa.

Others, however, do not think ſo highly of it, as it has been noticed in ſituations in the Highlands, where cattle were often ſtinted or ſtraightened for food, and generally remained untouched by them. The ſame has likewiſe been the caſe in other places of the above diſtricts.

Its ſtrong root is alſo thought an objection to its being cultivated as a graſs-crop, even if it were capable of it, as being difficult of extirpation.

It has been farther uſed for making cuſhions, to be put under the yokes uſed by oxen in ploughing; for which purpoſe it ſeems, it is ſaid, well ſuited, on account of its toughneſs. See Juncus.

SPRAWL, *To*, in *Military Language*, is to widen out in an irregular and unſoldier-like manner: a term chiefly applicable to the cavalry.

SPRAWLING Charge, a looſe and irregular movement of cavalry, inſtead of a cloſe, compact, forward attack.

SPRAY, in *Sea Language*, denotes the ſprinkling of the ſea, which is driven from the top of a wave in ſtormy weather. It differs from ſpoon-drift, as being only blown occaſionally from the broken ſurface of a high wave, whereas the latter continues to fly horizontally along the ſea, without intermiſſion, during the exceſs of a tempeſt or hurricane. Falconer.

Spray, in *Agriculture*, the twiggy branches of any ſort of underwood, which are uſeful for many different purpoſes. The ſpray of many extenſive woods, in different places, are cut over occaſionally for burning lime, &c.

Spray-*Faggots*, ſuch as are made from the ſpray or ſmall branches, and other offal, of different kinds of wood of the undergrowth kind, and bound up in proper quantities. This ſort of faggot, as well as thoſe which are made of furze, and ſome other inflammable matters, are much employed in burning chalk into lime, in what are called flame-kilns, in ſome diſtricts, as in Suſſex, &c.

SPREADING *and ſetting out Manure*, the practice of diſperſing and diſtributing it in or upon land, and putting it on in a proper manner for the purpoſe. This ſort of work is performed ſomewhat differently on arable or graſs-land, and according to the nature of the cultivation. This can never be done in the moſt proper and complete manner, unleſs the neceſſary attention has been beſtowed in ſetting the manure out, to ſee that it is not depoſited in too large heaps, but put out in equal proportions, of a moderate ſize, at pretty exact diſtances between the different heaps. In the buſineſs of ſetting out manure to the greateſt advantage, the carts employed ſhould be rather ſmall, and conveniently formed for the purpoſe. With large carts the work is liable to be done not only with much inequality, but in far too large heaps, ſo that it is done with great trouble and loſs of time. Single-horſe carts are perhaps, in general, the moſt uſeful in this way or intention.

The writer of the corrected account of the Agriculture of the County of Perth, has noticed an ingenious contrivance for facilitating the unloading of carts filled with ſubſtances of the manure kind, which is in uſe in that diſtrict. It conſiſts in ſuſpending the box or body-part of the cart at different heights, while it is emptying; but it can only be uſed with advantage in carts which are conſtructed on a ſort of moveable frame, or thoſe which are denominated coup-carts, and where the load is to be diſcharged in ſeveral different portions. For this purpoſe a thin piece of iron, of about two inches in breadth, is fixed on the fore-part of the box or body of the cart, exactly in the middle, extending in length to the top or height of the body or box-part, in which are formed and inſerted three or four oblong holes, correſponding in ſize to a rod or pin, which is fixed with a ſtaple in the middle of the firſt bar that keeps the ſhafts of the cart together. The length of this rod or pin is moſtly about eighteen inches, but longer when neceſſary, as the height or length of that part of the body or box of the cart which reſts on the frame may require. The top part of it is formed into ſomewhat the ſhape of a creſcent, an inch in width, with the point upwards, which correſponds with the holes in the iron plate. When the rod or pin is not in uſe, in order to prevent its dangling, it is made to reſt on a hook in the front of the box, or body of the cart. When the driver wiſhes or is deſirous to unload a part of the contents of the cart, he raiſes the box or body-part of it, putting the rod or pin into the firſt nick or hole, and makes the firſt heap; and then moves on to the place or diſtance where he intends to put down the ſecond, when he again raiſes the ſame part of the cart to the ſecond nick; continuing the ſame method until the whole of the contents be diſcharged or ſet out.

In ſpreading out manure on the ſurface of arable land, where it is to be turned into the ſoil by the plough, ſo much exactneſs is not neceſſary; though it ſhould always be done in as even and regular a manner, and to as equal a thickneſs, as poſſible. And on ridges, eſpecially where they are rather narrow, care ſhould be taken that it does not fall into the ridge-furrows, by carefully ſpreading it out at firſt all along the borders of them in a regular manner. In caſes where it is to be placed and ſpread out in drills or furrows made for the purpoſe, it ſhould conſtantly be executed in as even a manner, in regard to thickneſs, as it will readily permit, and in a way which will allow of its being covered in as completely as poſſible, as it is equally waſteful and diſgraceful to have it preſenting itſelf externally.

In ſpreading different ſorts of materials of the manure kind over graſs-land, it is always neceſſary to ſee that the work be performed in an exact and even manner, as well as that all the lumps and clods be well broken down, and as much reduced as poſſible, by beating them with the fork or ſhovel, or in ſome other way. On arable as well as graſs-land, as favourably dry a ſeaſon as can be obtained ſhould moſtly be choſen for this ſort of work. In wet ſeaſons, the materials clog and hang about the feet and tools of the workman, and are never capable of being ſo divided as to be ſpread out with the neceſſary degree of evenneſs and regularity, eſpecially on graſs-land. On this ſort of land, when the heaps have been ſet out, they ſhould never be ſuffered to remain ſo long as is too frequently the caſe, before they are ſpread out, as the graſs-plants underneath them become blanched and tender, and are liable to be deſtroyed; great injury being often done to the ſurface or ſward, in ſuch caſes. In ſpreading manure from the carts, injuries of this nature are likewiſe prevented, as is found in the midland and ſome other diſtricts, where the practice prevails; but in this mode, it is probable, the work can neither be performed in ſo perfect a manner, nor with ſo much economy of time and labour. In this manner, the inconvenience of hill or heap-ſteads will, however, be avoided; and, of courſe, the diſadvantage of their getting too large a proportion of manure guarded againſt and prevented

The tools moſtly employed in this ſort of work are thoſe of the dung-fork and the ſhovel, but others are occaſionally uſed for particular ſorts of manure.

After the ſubſtances of this kind have been ſpread out in this manner on graſs-land, they may often be farther uſefully reduced and diſtributed, by paſſing a buſh-harrow over them a few times in a dry ſeaſon, ſome weeks after the ſpreading has been performed.

Where manure, in its more recent or freſh ſtate, is employed either on arable or graſs-land, more attention will be neceſſary in ſpreading it out over or into the land, ſo that it may be done in an even and perfect manner. See YARD-*Dung*.

SPREE, or SPREHE, in *Geography*, a river which riſes on the frontiers of Bohemia, croſſes Luſatia, enters the marquiſate of Brandenburg, and, after paſſing by Berlin, joins the Havel at Spandau.

SPREMBERG, or SPREHENBERG, or *Grodk*, a town of Luſatia, on the river Spree, which gives name to a circle, or diſtrict; 29 miles S.S.W of Guben. N. lat. 51° 32′. E. long. 14° 25′.—Alſo, a town of Saxony, at the ſource of the Spree; 28 miles E. of Dreſden.

SPREMONT, a town of France, in the department of the Ourte, ſeated on a brook which runs into the Ourte, and together with a ſmall country, called the "Ban of Spremont," inſulated within the biſhopric of Liege; 13 miles S.W. of Liege.

SPRENDLINGEN, a town of France, in the department of the Rhine and Moſelle; 8 miles E. of Creutznach.

SPRENGELIA, in *Botany*, received that name from the writer of this article, in honour of Mr. Chriſtian Conrad Sprengel, maſter of a grammar-ſchool at Spandow, in Brandenburgh, who publiſhed at Berlin, in 1793, a moſt ingenious work, on the manner in which inſects promote the impregnation of plants. This fact is illuſtrated by ſeveral hundred particular examples, accompanied with figures of each. Dr. Curtius Sprengel, now Profeſſor of Botany at Halle, may alſo claim his ſhare of botanical commemoration in the above name. His *Prodromus* of a work on the arrangement of Umbelliferous Plants, publiſhed in 1813, to ſay nothing of his letters on Cryptogamic Vegetables, and his edition of the *Philoſophia Botanica* of Linnæus, may well entitle him to ſuch diſtinction.—Sm. in the Stockholm Tranſactions for 1794, 260. t. 8. Tracts relating to Nat. Hiſt. 269. Willd. Sp. Pl. v. 1. 833. Ait. Hort. Kew. v. 1. 320. Brown Prodr. Nov. Holl. v. 1. 554. (Poiretia; Cavan. Ic. v. 4. 24.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Ericæ*, Juſſ. *Epacrideæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, chaffy, coloured, in five deep, equal, lanceolate ſegments, erect after flowering, permanent. *Cor.* of one petal, wheel-ſhaped, beardleſs, in five very deep equal ſegments, the length of the calyx. Nectary none. *Stam.* Filaments five, inſerted into the receptacle, linear, flat, ſmooth, ſhorter than the corolla; anthers vertical, oblong, parallel, more or leſs combined, of one cell. *Piſt.* Germen ſuperior, roundiſh, depreſſed, with five furrows; ſtyle ſimple, cylindrical, about as long as the ſtamens; ſtigma obtuſe. *Peric.* Capſule ſomewhat cylindrical, obtuſe, with five furrows, of five valves and five cells, the partitions longitudinal, from the centre of each valve. *Seeds* numerous, roundiſh, minute, inſerted into the angles of the central column, which is ſhorter than the valves.

Eſſ. Ch. Calyx in five deep ſegments, permanent, coloured. Corolla wheel-ſhaped, in five deep ſegments, beardleſs. Stamens inſerted into the receptacle. Anthers converging or combined. Nectary none. Capſule of five valves and five cells, the partitions from the middle of each valve.

1. S. *incarnata*. Fleſh-coloured Sprengelia. Sm. Tracts, 272. t. 2. Willd. n. 1. Ait. n. 1. Br. n. 1. Andr. Repoſ. t. 2. (Poiretia cucullata; Cavan. Ic. t. 343. Lamarck Dict. v. 5. 449.)—Anthers combined, hairy. Calyx entirely coloured. Points of the leaves elongated.—Native of Port Jackſon, New South Wales; found alſo by Mr. Brown in Van Diemen's iſland, and on the ſouth coaſt of New Holland. Meſſrs. Lee and Kennedy raiſed the plant in 1793, and in their greenhouſes it ſtill flouriſhes, flowering from April to June. This is a pretty and ſingular *ſhrub*, about two feet high, rigid and much branched, leafy, ever-green, very ſmooth; the branches round. *Leaves* alternate, ſheathing, ſometimes imbricated in three ranks, recurved, lanceolate, acute, concave, entire, very ſmooth, rather glaucous, without rib or veins, tawny when faded, and finally looſened at their baſe, ſo as to turn round on the branch. *Stipulas* none. *Flowers* terminating the numerous, ſhort, crowded, lateral branches, clothed with ſmaller

leaves, and making a very pretty appearance. We do not find that they have any ſcent. *Calyx* roſe-coloured, half an inch in diameter. *Corolla* and *ſtamens* fleſh-coloured. The name of *Poiretia*, given by Cavanilles, was not publiſhed till three years after our *Sprengelia*.

2. S. *montana*. Mountain Sprengelia. Br. n. 2.—"Anthers unconnected, beardleſs. Calyx partly coloured. Points of the leaves ſhort."—Gathered by Mr. Brown in Van Diemen's iſland. We have ſeen no ſpecimens of this ſpecies.

Mr. Brown's PONCELETIA (ſee that article), as well as his *Anderſonia*, Prodr. Nov. Holl. v. 1. 553. Ait. Hort. Kew. v. 1. 321, ſeems very nearly related to the preſent genus, both in aſpect and character.

SPRETZA, in *Geography*, a river of Boſnia, which runs into the Boſna.

SPREWIL, a town of North Carolina, on the ſouth coaſt of Albemarle ſound. N. lat. 35° 56′. W. long. 76° 39′.

SPRIG, a ſmall eye-bolt, ragged at the point.

SPRIG is alſo a ſmall branch or ſpray. It likewiſe ſignifies a brad.

SPRIGE, in *Geography*, a townſhip of Ohio, in the county of Adams, containing 1664 inhabitants.

SPRIGNO. See SPIGNO.

SPRING, FONS, in *Natural Hiſtory*, a fountain or ſource of water, riſing out of the ground.

The origin of ſprings or fountains has been much controverted among our late naturaliſts. Meſſrs. Mariotte and Perrault aſcribe them to rain, to which others have added dew; their doctrine is, that the rain-water penetrates the earth till ſuch time as it meets a clayey ſoil, or ſtratum; which proving a ſufficient ſolid bottom to ſuſtain and ſtop its deſcent, it glides along it that way to which the earth declines, till meeting with a place, or aperture, on the ſurface, through which it may eſcape, it forms the head of a river.

Now, that the rain is ſufficient for this effect, appears hence; that, upon calculating the quantity of rain and ſnow which falls yearly on the tract of ground, that is to furniſh, for inſtance, the water of the Seine, it is found that river does not take up above one-ſixth part of it.

Springs ordinarily ariſe at the bottom of mountains: the reaſon, they ſay, is, that mountains collect the moſt waters, and give them the greateſt deſcent the ſame way: and that if we ſometimes ſee ſprings on high grounds, and even on the tops of mountains, they muſt be brought from other remoter places conſiderably higher, along beds of clay, or clayey ground, as in their natural channels. If, then, there happen to be a valley between a mountain on whoſe top is a ſpring, and the mountain that is to furniſh it with water, the ſpring muſt be looked on as water conducted from a reſervoir of a certain height through a ſubterraneous channel, to make a jet of an equal or ſomewhat leſs height.

This theory M. de la Hire (Pariſian Mem. for 1703) has taken under examination, in its moſt eſſential article, and that where the authors ſeem to have been the leaſt diſtruſtful. He has endeavoured to find by experiment, whether rain or ſnow-water could penetrate the earth as low as the clayey ſtratum: with this view he procured a leaden veſſel eight feet deep, having a pipe at the bottom: this he buried in the earth, and filled with ſoil of ſand and loam, expoſing the ſurface to receive all the rain that fell. After fifteen years' trial, he found that no water had run through the pipe at the bottom. Again, he took another veſſel, eight inches deep, which he filled with earth, and expoſed in like manner. No rain penetrated ſo as to run out at the bottom from June to February; but after that time it yielded a quantity after moſt rains. Another veſſel of twice the depth, or ſixteen inches, gave a reſult much like that of eight inches. When herbs were planted in this laſt-mentioned veſſel, he found that as ſoon as ever any of theſe came up, and were grown to any bulk, ſo far was the rain that fell from being able to gather itſelf at the depth of ſixteen inches, that it was not ſufficient even to feed the plants, but there was a neceſſity for watering them.

With reſpect to the firſt-mentioned fact, ſays Mr. Dalton, (Mancheſter Memoirs, vol. v.) we need not wonder that no water penetrated through eight feet of earth at Paris, where the annual rain is but 20 inches, when only eight or nine inches penetrated through three feet of earth here, where the rain is 33 or 34 inches annually. But it does not follow, that rain may not deſcend down declivities of the ground into vallies or lower parts, at Paris as well as here, and being accumulated, may penetrate into the earth to a conſiderable depth, eſpecially if it meet with channels or chaſms of any kind, or declining ſtrata of earth, that are impenetrable by water. Paris, Mr. Dalton believes, however, is not very liberally ſupplied with ſprings, as might be expected. As to the experiment upon vegetation, it only proves that the rain in ſpring and ſummer is ſometimes not ſufficient to ſupport vegetable life, a fact which may readily be granted; but then in his experiment the plants were precluded from a ſupply of moiſture from the earth beneath the veſſel, which is a reſerve of the utmoſt conſequence in dry ſeaſons.

This circumſtance of water aſcending again in the earth, on whatever principle it is effected, cannot be denied. There were four inches and three-quarters of rain here in July laſt, none of which paſſed through the earth in the evaporating veſſel; this earth, however, at the end of the month, was far from that degree of dryneſs which is unfit for the ſupport of vegetation. During the firſt four days of Auguſt there fell about three inches of rain, and only half an inch penetrated through the earth in the evaporating veſſel. Conſequently three feet in depth of earth that was moderately moiſt imbibed nearly three inches of rain, before it was ſaturated; whence we may conclude, that three inches nearly had aſcended and been evaporated. This evidently ſhews, that earth is capable of holding a very great proportion of water, that in ſummer the water aſcends to ſupply the exigencies at the ſurface, and that earth far under the point of ſaturation with moiſture is ſtill fit to ſupport vegetation.

This obſervation ſuggeſted the following queſtion—How much water is there in a given depth of earth, when the ſoil is at the point of ſaturation, or in that ſtate, when it begins to yield water from the lower pipe of the evaporating gauge?

To determine this, Mr. Dalton took a quantity of garden ſoil, that had been ſoaked with rain a day before, and preſſed it into a crucible; in this ſtate he found its ſpecific gravity to that of water, as five to three. It was then expoſed to a moderate heat, till it appeared, as near as he could judge, of the ſame moiſture as garden ſoil two inches deep in dry ſummer weather; afterwards it was expoſed almoſt to a red heat, till it became a perfectly dry powder; in the former caſe it loſt one-twelfth of its weight, and in the latter one-third. When it had loſt one-ſixth, it did not appear too dry to ſupport vegetation. When it had loſt two-ninths, it appeared like the top ſoil in ſummer. Hence it follows, that every foot of earth in depth, ſo ſaturated, contains ſeven inches of water, and that it may part with a quarter of its water, or even a half, and not be too dry for ſupporting vegetation.

Clay, juſt dug out for the purpoſe of making bricks, was tried in the ſame manner. It gave the ſame ſpecific gravity as the earth, and yielded not much leſs water.

Theſe experiments and obſervations prove, that M. de la Hire's concluſions, drawn from the vegetation of plants in a given quantity of ſoil, precluded from any communication with the earth at large, are erroneous, or at leaſt unwarranted; as it does not thence appear, that the evaporation for the whole year exceeds the rain in the year, whatever it may do for a month or two in ſummer.

The origin of ſprings may ſtill, therefore, be attributed to rain, till ſome more deciſive experiments appear to the contrary.

Upon the whole it ſhould ſeem, that at the commencement of ſpring, the ground is nearly ſaturated with water for five or ſix feet in depth, as the rains and dews in autumn and winter far exceed the evaporation. There are then five or ſix inches of water at leaſt to be raiſed up again to the ſurface in caſe of exigence in the ſpring and ſummer. If this happen to be ſo, then it is at the expence of ſprings; for we find the generality of ſprings become languid, or entirely ceaſe to flow at the end of a long drought. As to the few ſprings that ſeem to be little affected by dry or wet ſeaſons, they form exceptions, which it would not be difficult to account for. See Evaporation.

Dr. Halley refers the origin of ſprings merely to vapours raiſed by the heat of the ſun, or of ſubterraneous fires, from the ſea, lakes, rivers, &c.

Now, to ſhew that vapour is a ſufficient fund to ſupply all our ſprings, rivers, &c. the ſame excellent author makes an eſtimate of the quantity of vapour raiſed from the Mediterranean ſea, by the action of the ſun: for the reſult of which, ſee Vapour.

Yet the quantity of water thus raiſed, great as it is, is only the remains of what is raiſed another way; *viz.* by the winds, which ſometimes ſweep the water off much faſter than the ſun takes it up.

To find, now, the quantity of water the Mediterranean receives, allow the moſt conſiderable rivers it receives, *viz.* the Iberus, Rhone, Tiber, Po, Danube, Neiſter, Boryſthenes, Tanais, and the Nile, each to furniſh ten times as much water as the Thames; not that any of them are in reality ſo great, but ſo to allow for the leſſer rivulets; but the Thames is found, by calculation, to evacuate 20,300,000 tons of water daily. All the nine rivers above-mentioned, therefore, will only evacuate 1827 millions of tons in a day; which is little more than a third of what is raiſed in that time in vapour. The whole Mediterranean, according to calculation, is computed to contain 160 ſquare degrees, yielding at leaſt 5280 millions of tons. (Phil. Tranſ. N° 189. or Abr. vol. ii. p. 110.) For a more correct eſtimate by Mr. Dalton, ſee River.

The prodigious quantity of water remaining, Dr. Halley allows to rains, which fall again into the ſeas, and for the purpoſes of vegetation, &c. As to the manner in which this water is collected, ſo as to form reſervoirs for the different kinds of ſprings, it ſeems to be this: the tops of mountains, in general, abound with cavities and ſubterraneous caverns, formed by nature to ſerve as reſervoirs; and their pointed ſummits, which ſeem to pierce the clouds, ſtop thoſe vapours which fluctuate in the atmoſphere, and being condenſed by them, they precipitate in water, and by their gravity eaſily penetrate through beds of ſand and lighter earth, till they are ſtopped in their deſcent by more denſe ſtrata, as beds of clay, ſtone, &c., where they form a baſon or cavern, and work a paſſage horizontally, and iſſue out at the ſides of the mountains. Many of theſe ſprings diſcharge water, which running down between the ridges of hills, unite their ſtreams, and form rivulets or brooks; and many of theſe uniting again on the plain, become a river.

After all that can be ſaid in favour both of rain and vapour, it muſt be owned, they are both ſtill encumbered with great difficulties; though by no means inſuperable.

The perpetuity of divers ſprings, always yielding the ſame quantity of water, when the leaſt rain or vapour is afforded as well as the greateſt, is a ſtrong objection to both. Dr. Derham mentions one in his own pariſh of Upminſter, which he could never perceive by his eye to be diminiſhed in the greateſt droughts, even when all the ponds in the country, as well as an adjoining brook, had been dry for ſeveral months together; nor ever to be increaſed in the moſt rainy ſeaſons, excepting perhaps for a few hours, or at moſt for a day, from ſudden and violent rains. Had this ſpring its origin from rain or vapour, there would be found an increaſe and decreaſe of its water correſponding to thoſe of its cauſes; as we actually find in ſuch temporary ſprings as have undoubtedly their riſe from rain and vapour: add to this, another conſiderable thing in this Upminſter ſpring, and thouſands of others; *viz.* that it breaks out of ſo inconſiderable an hillock, or eminence, as can have no more influence in the condenſation of the vapours, or ſtopping the clouds, than the lower lands about it have. The very higheſt ground in the country he finds is not above a hundred and thirty-three yards above the level of the ſea; and what is ſuch an inconſiderable riſe of land, to perennial condenſation of vapours, fit to afford ſo conſiderable a ſpring? or the high lands of the whole country, to the maintaining all its fountains and rivulets?

Other naturaliſts, therefore, have had recourſe to the ſea, and derive the original of ſprings immediately thence; but how the ſea-water ſhould be raiſed up to the ſurface of our earth, and even to the tops of the mountains, is a difficulty, in the ſolution of which they cannot agree. Some fancy a kind of hollow ſubterranean rocks to receive the watery vapours raiſed from channels communicating with the ſea, by means of an internal fire, and to act the part of alembics, in freeing them from their ſaline particles, as well as condenſing and converting them into water. This kind of ſubterranean laboratory, ſerving for the diſtillation of ſea-water, was the invention of Deſcartes. (Princip. part iv. § 64.) Others, as M. de la Hire (Mem. de l'Acad. an. 1703), &c. ſet aſide the neceſſity of alembics, and think it enough that there be large ſubterranean reſervoirs of water at the height of the ſea, whence the warmth of the bottom of the earth, or even the central fire (if there be ſuch a thing), may raiſe vapours; which, pervading not only the intervals and fiſſures of the ſtrata, but the bodies of the ſtrata themſelves, at length arrive near the ſurface; where, being condenſed by the cold, they glide along on the firſt bed of clay they meet with, until an aperture in the ground lets them out. M. de la Hire adds, that the ſalts of ſtones and minerals may contribute to the detaining and fixing the vapours, and converting them into water. But we have a ſtill more natural and eaſy way of exhibiting the riſe of the ſea-water up into mountains, &c. by putting a little heap of ſand, aſhes, a loaf of bread, or the like, into a baſon of water; in which caſe the ſand, &c. will repreſent the dry land, or an iſland; and the baſon of water the ſea about it. Here the water in the baſon will riſe to or near the top of the heap, in the ſame manner, and from the ſame principle, as the waters of the ſea, lakes, &c. riſe in the hills. The principle of aſcent in both is accordingly ſuppoſed to be the ſame with that of the aſcent of liquids in capillary tubes, or between contiguous planes, or in a tube filled with aſhes; all which are now generally accounted for from the doctrine of attraction. See RIVER.

Againſt this laſt theory, M. Perrault and others have urged ſeveral unanſwerable objections. It ſuppoſes a variety of ſubterranean paſſages and caverns, communicating with the ſea, and a complicated apparatus of alembics, heat and cold, &c. of the exiſtence of which we have no ſufficient proof. Beſides, the water that is ſuppoſed to aſcend from the depths of the ſea, or from ſubterranean canals proceeding from it, through the porous parts of the earth, as it riſes in capillary tubes, aſcends to no great height, and in much too ſmall a quantity, to furniſh ſprings with water, as M. Perrault has ſufficiently ſhewn. And though the ſand and earth through which the water aſcends may acquire ſome ſaline particles from it, they are nevertheleſs incapable of rendering it ſo freſh as the water of our fountains is generally found to be. Not to add, that in proceſs of time, the ſaline particles of which the water is deprived, either by ſubterranean diſtillation or filtration, muſt clog and obſtruct thoſe canals and alembics by which it is ſuppoſed to be conveyed to our ſprings, and the ſea muſt likewiſe gradually loſe a conſiderable quantity of its ſalt.

In ſpeaking of the ſituation of the earth, as connected with the formation of ſprings, Dr. Darwin has obſerved, that it conſiſts of ſtrata, many of which were formed originally beneath the ſea. The mountains were afterwards forced up by ſubterraneous fires, as appears from the fiſſures in the rocks of which they conſiſt, the quantity of volcanic productions all over the world, and the numerous remains of craters of volcanoes in mountainous countries. Hence it is contended, that the ſtrata which compoſe the ſides of mountains lie ſlanting downwards, and that one or two, or more, of the external ſtrata not reaching to the ſummit when the mountain was raiſed up, the ſecond or third ſtratum, or a ſtill more inferior one, is there expoſed to day; this may be well repreſented, it is ſaid, by forcibly thruſting a blunt inſtrument through ſeveral ſheets of paper, a bur will ſtand up with the lowermoſt ſheet ſtanding higher in the centre of it. On this uppermoſt ſtratum, which is colder as it is more elevated, the dews are condenſed in large quantities, and ſliding down, paſs under the firſt or ſecond or third ſtratum, which compoſe the ſides of the hill; and either form a moraſs below, or a weeping rock, by oozing out in numerous places, or many of theſe leſs currents meeting together, burſt out in a more copious rill.

But that, as the ſprings conſiſt of the water which ſlides down between thoſe inclined ſtrata; it is evident that, in ſome eminences of ground they are only to be met with on one ſide of the mountain; and in other eminences of ground, on all ſides of it. In ſearching for ſprings, therefore, attention ſhould be given to the inclination of the ſtrata of that part of the country, which may be often ſeen in marle-pits, gravel-pits, or in hollow lanes. But they may in general be found above any moiſt or moraſſy place, or valley; the moiſture of which ſhews that ſprings exiſt in the ſtrata on that ſide of the hill or mountain. And another obſervation for the purpoſe of detecting ſprings, may, it is ſaid, be made on miſty evenings; as thoſe parts of the ground where the miſt commences, are moiſter than thoſe in their vicinity on the ſame level, and in conſequence may generally, if they are not hollow baſons, poſſeſs ſprings nearer the ſurface; for theſe moiſter parts of the ground, having evaporated more during the day, are become colder on their ſurfaces than the drier ground in their vicinity; and in miſty evenings, which are at the ſame time calm, the ſtationary air over theſe moiſt parts of the ground is alſo more loaded with the evaporated moiſture; and on both theſe accounts, theſe moiſter ſituations are liable to ſhew a condenſation of aerial vapour ſooner than other places on the ſame level. And there may be other cauſes of ſprings in the nature of hilly ſituations, for as mountains are colder in proportion to their height, 1ſt, their being in a manner inſulated or cut off from the common heat of the earth, which is always of 48°, and perpetually counteracts the effects of external cold beneath that degree, may be one cauſe. 2. From their ſurfaces being larger in proportion to their ſolid contents, and hence their heat more expeditiouſly carried away by the ever moving atmoſphere. 3. The increaſing rarity of the air as the mountain riſes. All thoſe bodies which conduct electricity well or ill, conduct the matter of heat likewiſe well or ill. Atmoſpheric air is a bad conductor of electricity, and thence confines it on the body where it is accumulated; but when it is made very rare, as in the exhauſted receiver, the electric aura paſſes away immediately to any diſtance. The ſame circumſtance probably happens in reſpect to heat, which is thus kept by the denſer air on the plains from eſcaping, but is diſſipated on the hills, where the air is thinner. 4. As the currents of air riſe up the ſides of mountains, they become mechanically rarefied, the preſſure of the incumbent column leſſening as they aſcend. Hence the expanding air abſorbs heat from the mountains as it aſcends. 5. There is another, and perhaps more powerful cauſe, it is ſuſpected, which may occaſion the greater cold on mountains, and in the higher parts of the atmoſphere, and which has not yet been attended to; it is meant that the fluid matter of heat may probably gravitate round the earth, and form an atmoſphere, which may diminiſh or become rarer, as it recedes from the earth's ſurface, in a greater proportion than the air diminiſhes. And the greater condenſation of moiſture on the ſummits of hills has another cauſe, which is the daſhing of moving clouds againſt them; in miſty days this is often ſeen to have great effects on plains, where an eminent tree, by obſtructing the miſt as it moves along, ſhall have a much greater quantity of moiſture drop from its leaves, than falls at the ſame time on the ground in its vicinity. Hence it is concluded, as ſuggeſted above, that the evening miſt commences ſooner on them than in the vallies, but is ſeen earlier in the ſituations over the moiſter places, if they are on the ſame level with the drier ones, exactly as on the plains or vallies; and may therefore indicate the exiſtence of ſprings, unleſs theſe moiſter places conſiſt of hollow baſons, containing water, which, if not attended to, may in all ſituations deceive the obſerver. And further obſervations for detecting ſprings may be made in rimy mornings; for as moiſt earth is a better conductor of heat than dry earth, the rime will ſooner melt on thoſe parts of the ſoil which are kept moiſt by ſprings under it than in other parts; as the common heat of the earth, which is 48° in this country, will ſooner be conducted upwards in moiſt places to diſſolve the rime on the ſurface. On this account the rime is frequently ſeen on froſty mornings, when the heat of the air is not much above 32°, to lie an hour longer on dry cakes of cow-dung, or on bridges, or planks of wood, than on the common moiſt ground, as the latter much better conducts the common heat of the earth to the incumbent rime which is in contact with it. But as the heat of the common ſprings in this country is 48°, where they exiſt, the rime is ſooner diſſolved than on the ſtagnant moiſture of bogs or moraſſes. It is therefore concluded, that the common cold ſprings are thus formed on elevated grounds by the condenſed vapours, and hence are ſtronger when the nights are cold, after hot days in ſpring, than even in the wet days of winter. For the warm atmoſphere during the day has diſſolved much more water than it can ſupport in ſolution during the cold of the night, which is thus depoſited in large quantities on the hills, and yet ſo gradually, as to ſoak in between the ſtrata of them, rather than to ſlide off over the ſurfaces, like ſhowers of rain. The common heat of the internal parts of the earth is aſcertained by ſprings which ariſe from the ſtrata of earth too deep to be affected by the heat of the ſummer, or the froſts of winter. Thoſe in this country, as has been ſeen, are of 48° of heat, thoſe about Philadelphia were ſaid by Dr. Franklin to be 52°. Whether this variation is to be accounted for by the difference of the ſun's heat in that country, according to the ingenious theory of Mr. Kirwan, or to the vicinity of ſubterranean fires, is not yet, it is thought, decided. And in the winter months, the riſe of ſprings may be detected in moiſt ditches by the preſence of aquatic plants, as of the water-creſs, water-parſnip, brooklime, &c.; as in thoſe ditches which become dry in ſummer theſe plants do not exiſt; and when thoſe ditches with ſprings in them are nearly dry, it may be diſcovered which way the current has formerly deſcended, by the direction of the points of the leaves of aquatic plants, as certainly as by a level; an obſervation which was learnt from Mr. Brindley, the great canal conductor of Staffordſhire.

The proper application of theſe principles may lead to many uſeful concluſions, both in reſpect to agriculture and rural economy, and is a ſort of knowledge which thoſe engaged in the providing of water for wells or pits ſhould be well acquainted with. See Draining, Water, and Well.

For the method of preventing or remedying the injury done to land by ſprings, &c. ſee Spring-*Draining*.

Springs, *Different Sorts of*. Springs are either ſuch as run continually, called *perennial;* or ſuch as run only for a time, and at certain ſeaſons of the year, and therefore called *temporary* ſprings. Others, again, are called *intermitting* ſprings, becauſe they flow and then ſtop, and flow and ſtop again; and *reciprocating* ſprings, whoſe waters riſe and fall, or flow and ebb, by regular intervals, which are alſo called "ebbing and flowing wells." In order to account for theſe differences in ſprings, let A B C D E (*Plate* XV. *Hydraulics*, *fig.* 7.) repreſent the declivity of a hill, along which the rain deſcends; paſſing through the fiſſures or channels B F, C G, D H, and L K, into the cavity or reſervoir F G H K M I; from this cavity let there be a narrow drain or duct K E, which diſcharges the water at E. As the capacity of the reſervoir is ſuppoſed to be large in proportion to that of the drain, it will furniſh a conſtant ſupply of water to the ſpring at E. But if the reſervoir F G H K M I be ſmall, and the drain large, the water contained in the former, unleſs it is ſupplied by rain, will be wholly diſcharged by the latter, and the ſpring will become dry; and ſo it will continue, even though it rains, till the water has had time to penetrate through the earth, or to paſs through the channels into the reſervoir; and the time neceſſary for furniſhing a new ſupply to the drain K E, will depend on the ſize of the fiſſure, the nature of the ſoil, and the depth of the cavity with which it communicates. Hence it may happen, that the ſpring at E may remain dry for a conſiderable time, and even whilſt it rains; but when the water has found its way into the cavity of the hill, the ſpring will begin to run. Springs of this kind, it is evident, may be dry in wet weather, eſpecially if the duct K E is not exactly level with the bottom of the cavity in the hill, and diſcharge water in dry weather; and the intermiſſion of the ſpring may continue for ſeveral days. But if we ſuppoſe X O P to repreſent another cavity, ſupplied with water by the channel N O, as well as by fiſſures and clefts in the rock, and by the draining of the adjacent earth; and another channel S T V, communicating with the bottom of it at S, aſcending to T, and terminating on the ſurface at V, in the form of a *ſiphon* (which ſee); this diſpoſition of the internal cavities of the earth, which we may reaſonably ſuppoſe that nature has formed in a variety of places, will ſerve to explain the principle of reciprocating ſprings. For it is plain that the cavity X O P muſt be ſupplied with water to the height Q P T, before it can paſs over the bend of the channel at T, and then it will flow through the longer leg of the ſiphon T V, and be diſcharged at the end V, which is lower than S. Now if the channel S T V be conſiderably larger than N O, by which the water is principally conveyed into the reſervoir X O P, the reſervoir will be emptied of its water by the ſiphon; and when the water deſcends below its orifice S, the air will drive the remaining water out of the crooked channel S T V, and the ſpring will ceaſe to flow. But in time the water in the reſervoir will again riſe to the height Q P T, and be diſcharged at V, as before. It is eaſy to conceive, that the diameters of the channels N O and S T V may be ſo proportioned to one another, as to afford an intermiſſion and renewal of the ſpring V at regular intervals. Thus, if N O communicates with a well ſupplied by the tide, during the time of flow, the quantity of water conveyed by it into the cavity X O P, may be ſufficient to fill it up to Q P T; and S T V may be of ſuch a ſize as to empty it, during the time of ebb. It is eaſy to apply this reaſoning to more complicated caſes, where ſeveral reſervoirs and ſiphons, communicating with each other, may ſupply ſprings, with circumſtances of greater variety. See Muſchenbroeck's Introd. ad Phil. Nat. tom. ii. p. 1010. Deſag. Ex. Phil. vol. ii. p. 173, &c.

We ſhall here obſerve, that Deſaguliers calls thoſe *reciprocating* ſprings which flow conſtantly, but with a ſtream ſubject to increaſe and decreaſe; and thus he diſtinguiſhes them from *intermitting* ſprings, which flow or ſtop alternately.

It is ſaid, that in the dioceſe of Paderborn, in Weſtphalia, there is a ſpring which diſappears twice in twenty-four hours, and always returns at the end of ſix hours with a great noiſe, and with ſo much force, as to turn three mills not far from its ſource. It is called the *bolder-born*, or boiſterous ſpring. Phil. Tranſ. N° 7. p. 127.

There are many ſprings of an extraordinary nature in our own country, which it is needleſs to recite, as they are explicable by the general principles already illuſtrated.

Springs are farther divided into *oozing* or *weeping* ſprings, where the water gently trickles through the pores of the land; *pipe* ſprings, where they appear in a ſingle rill; and *wall* ſprings, where the water iſſues, as it were, through the joints of a wall. But beſides theſe, ſprings have many other local names, which ſerve to diſtinguiſh them in their particular ſituations, where they break out in grounds. See Spring-*Draining*.

Springs, *Burning*, or *Boiling*. The burning ſpring near Grenoble, in Dauphiné, is famous. St. Auguſtine ſpeaks of it as extinguiſhing lamps which are lighted, and lighting thoſe which are extinct. But it is now cold, like others; only near it is a ſpot of ground, which ſtill emits a light flame; over which ſome imagine it might anciently have paſſed. Auguſt. de Civ. Dei, lib. xxi. cap. 7, and 11. Mem. Acad. Inſcript. tom. ix. p. 565. Mem. Acad. Scien. an. 1699, p. 26.

At Boſeley, near Wenlock, in Shropſhire, there is a famous boiling well, which was diſcovered in June 1711, by an uncommon noiſe in the night, ſo great, that it awakened ſeveral people, who being deſirous to find what it was owing to, at length found a boggy place under a little hill, not far from the Severn; and perceiving a great ſhaking of the earth, and a little boiling up of water through the graſs, they took a ſpade, and digging up ſome part of the earth, the water flew to a great height, and was ſet on fire by a candle. This water was for ſome time afterwards conſtantly found to take fire, and burn like ſpirit of wine; and after it was ſet on fire, it would boil the water in a veſſel ſooner than any artificial fire, and yet the ſpring itſelf was as cold as any whatever. Phil. Tranſ. No. 334.

This well was at length loſt for many years, and not recovered till May, 1746, when by a rumbling noiſe under ground, like to what the former well made, it was hit upon again, though in a lower ſituation, and thirty yards nearer the river.

The well is four or five feet deep, and ſix or ſeven wide; within that is another leſs hole of like depth, dug in the clay, in the bottom of which is placed a cylindric earthen veſſel, of about four or five inches diameter at the mouth, having the bottom taken off, and the ſides well fixed in the clay, rammed cloſe about it. Within the pot is a brown water, thick as puddle, continually forced up by a violent motion, beyond that of boiling water, and a rumbling hollow noiſe, riſing and falling by fits five or ſix inches. It may be fired by a candle at a quarter of a yard diſtance; and it darts and flaſhes in a violent manner, about half a yard high. It has been left burning forty-eight hours, without any ſenſible diminution. It may be extinguiſhed by putting a wet mop upon it, which muſt be kept there a ſmall time. On the removal of the mop there ſucceeds a ſulphureous ſmoke, laſting about a minute, and yet the water is very cold to the touch. Phil. Tranſ. No. 482, ſect. 6.

SPRING, *Lancarim*. See LANCARIM.

SPRINGS, *Medicinal*. See WATER.

SPRINGS, *Artificial*, thoſe kinds of ſprings, or collections of water, which are made by art in different views and intentions, by the farmer and land proprietor.

The methods of proceeding in theſe ſorts of undertakings may be thoſe of making a ſufficient number of under-drain ſprings for the purpoſe of the above kind, in different directions, ſo as that they may unite in one, at or near their terminations in the wells or ciſterns, as, in theſe ways, the water may be drawn from a much larger ſpace of ground than would otherwiſe be the caſe, and, of courſe, better ſupplies of water be afforded.

Country-houſes and reſidences may ſometimes be ſupplied with good water in ſomewhat this way, where there is either a deficiency in the quantity or quality of that which is provided. A very diſtinguiſhed proprietor in the county of Berks, E. L. Loveden, eſq. of Buſcot Park, had recourſe, it is ſaid, to the following very ingenious and ſucceſsful contrivance, in order to accompliſh this purpoſe, which deſerves to be particularly noticed, as it may be applicable to many other ſituations, where the ſcarcity of water, or of ſuch as is good, is felt. It is ſtated in the Agricultural Report of the above diſtrict, that, the ſeat of this proprietor ſtanding near the very brow of the eminence on which it is built, there was only a ſuperficies of about an acre and a half of graſs-land in front, from which there was not the leaſt deſcent. A ſemicircular drain with a mole-plough, ſcarcely perceptible on walking over the ground, in the line of the greateſt elevation, was made to communicate with two ſmall iron grates on the ſide of the gravel-drive up to the principal front. All the water which falls on this drive paſſes to one or other of thoſe grates, between which there is an under-ground drain, with a very moderate fall to that which is the moſt weſterly, where a channel commences which is capable of receiving all the water within the compaſs of the ſemicircular drain, and which paſſing through proper ſtrainers, is conveyed to a large ſunk reſervoir, in a court to the weſtward of the manſion; and a pump being placed there, the family is ſupplied, it is ſaid, with a pure ſoft water, no leſs ſalutary than uſeful for every domeſtic purpoſe.

Springs of the above artificial kind may likewiſe be applicable in many other caſes, where there is a want of water for particular uſes.

SPRINGS, *Land*, ſuch of the more ſuperficial kind as riſe and exiſt in ſituations where the collecting ſurface of the water, together with the containing ſtratum, are of a rather ſmall and confined extent. They are often met with about the baſes of hilly lands, on ſlopes, at the feet of the little riſings in valley tracts, in their variouſly mixed banks, as well as in many other ſituations and circumſtances of land. The term is alſo ſometimes applied to the drains which are made by art for the procuring of water for different purpoſes.

They are always ſuch as are of the more ſuperficial kind. The writer of the work on "Landed Property" conſiders theſe ſprings as partial effects, partaking of the nature of cold, or of weak lands, according to the quality of the ſoil that covers them. They may, it is ſaid, be conſidered as the moſt common diſeaſe of land where water is concerned.

It is ſuppoſed that the cauſes of theſe ſorts of ſprings are moſtly of a topical nature, the diſeaſe being commonly produced by rain-water falling on an abſorbent ſoil which has a broken ſub-ſtratum. A broad, flat-topped ſwell of ſandy or gravelly loam, beſet with plots or maſſes of clay, is, it is thought, ſingularly productive of this ſort of watery lands. The means of remedying the injurious wetneſſes ariſing from theſe kinds of ſprings, are ſhewn in ſpeaking of ſpring-draining. See SPRING-*Draining*.

SPRING-*Drain*, that ſort of drain or channel which is prepared and conſtructed in land for the purpoſe of taking away ſuch kinds of over-wetneſs in it, as is cauſed by internal or other ſprings. Theſe drains are made in many different methods, according to the nature and circumſtances of the grounds, and the degrees of the wetneſſes which are preſent in them; but, for the moſt part, in a deeper and more ſubſtantial manner than in the other modes of forming drains.

Drains of this ſort are conſtructed of many different kinds of materials, but moſtly of thoſe which are of the more ſolid and durable deſcriptions, ſuch as the common brick, bricks made in different forms and ſhapes for the purpoſe, pipes made in different ways, flat ſtones of the free-ſtone and other kinds, common ſtones laid in different modes, and ſome other ſimilar ſubſtances. Where common bricks are employed, they are often built in a firm manner on the ſides and arched over the tops, but in other caſes laid lengthwiſe over each other to the neceſſary height, and then covered over with flat ſtones, and the earth filled in upon them. They have alſo other modes of conſtruction, which are ſometimes much leſs expenſive, according to the nature of the drainage, as will be more fully ſeen and explained in ſpeaking of ſurface-drains. But where bricks made for the purpoſe are uſed in theſe caſes, other methods are followed. There are many different forms of bricks contrived in this intention; one of which is ſo conſtructed, as to form, when laid, a ſmall neat arched drain four inches in diameter, and is principally made uſe of where only ſmall drains are neceſſary, as in the conveying of the water of ſprings to houſes and other buildings, &c. A ſecond ſort is made of three pieces, ſo as to conſtitute a ſquare drain ſix inches in width and height; and a third kind is formed with a circular opening ſix inches in diameter, having long ſquare openings in the top part, and light parts two inches in breadth, to reſt upon, on the ſides. It was invented by Mr. Couchman, of Boſworth Temple, in the county of Warwick. The two laſt ſorts are well ſuited for forming large drains, but more eſpecially the latter. In ſtiff ſoils, they are for the moſt part beſt when laid ſingly, without any common bricks or tiles being placed underneath them; but in light ſandy lands, it is moſtly better to lay common bricks, or ſtrong tiles, under their ſides, in order to prevent their ſinking down into the ſoil too much. See SPRING-*Draining*.

Another ſort of bricks that may be employed in this way, it is ſuppoſed, with ſtill greater advantage than the above, has been invented by John Aſhworth of Turton, near Bolton, in the county of Lancaſter. Theſe are contrived in different forms and ſhapes, ſo as to be laid in different manners, and form different ſorts of openings. When they are placed in ſuch a manner as to conſtitute a ſort of incloſed triangular opening for the diſcharge of the water from the land, eighty-four bricks are required to every eight yards; while with common bricks, one hundred and ninety are neceſſary. There is conſequently a ſaving, by this means, of one hundred and ſix bricks in every eight yards of draining that is performed. By another form of theſe bricks, laid ſo as to ſlant againſt each other, without any thing under them, fifty-five bricks are only neceſſary for draining eight yards in length; and, of courſe, one hundred and thirty-ſeven bricks are ſaved in that extent. In another form in which theſe bricks are laid, which repreſents a ſort of incloſed diamond-formed opening, one hundred and ten bricks of this kind are taken to complete the ſame length of drain, by which eighty-two bricks are ſaved. This form is, however, only neceſſary where the quantities of water to be carried off, or taken away, are very large. In a further different form and manner of laying theſe bricks, the ſame number are made uſe of as in the firſt caſe, and the ſaving of common bricks is in the ſame proportion. A farther ſtill different form and manner of laying theſe bricks, employs them in the ſame proportion as in the third caſe, and ſaves common bricks in the ſame extent. This is particularly uſeful in the drainage of boggy, ſwampy, ſoft lands, and where quickſands are preſent. There is yet another form and manner of laying theſe bricks, which ſaves common bricks in the ſame manner as in the ſecond of the above caſes. And there is, laſtly, a ſtill different form and manner of laying theſe bricks, which takes them in the ſame quantities as in the third and fifth caſes above, and conſequently ſaves common bricks in the ſame proportion as they do. See SPRING-*Draining Bricks*.

It is not improbable but that bricks for this purpoſe may have been invented by other perſons, in different other diſtricts, which may anſwer well for forming ſpring-drains in different caſes. See SURFACE-*Drain*, and SUBSOIL *Brick-Drain*.

Drains formed of theſe materials, though they are commonly very effectual for the purpoſe, are in general attended with conſiderable expence.

Large pipes formed of burnt clay, and ſome other ſorts of materials, are not unfrequently employed in the making of drains of this nature, as well as in ſome caſes for thoſe of the ſurface kind.

Where ſtones are made uſe of in conſtructing drains, for the purpoſe of carrying off the water of ſprings, there are ſeveral different modes of laying them. They are ſometimes built up on the ſides, to the neceſſary heights and widths, by the ſmaller ſtones, and then covered over the tops, and connected by the large flat ones of the freeſtone, limeſtone, or other ſimilar kinds: at other times, the flat ſtones, whether of the freeſtone, limeſtone, or other ſorts, are ſet up edgeways in the bottoms of the drains, in a kind of triangular manner, or, which is better, in ſomewhat the form of the reverted letter A, the latter being laid over on the tops with broad flat ſtones. Theſe conſtitute excellent cheap drains.

There are alſo ſeveral other matters of this nature, as thoſe of the flaggy and ſlaty kinds, which may be uſed for this purpoſe, with equal advantage in different ſituations. See SURFACE-*Drain*.

It has been ſuggeſted, that in conſtructing main drains of this ſort for carrying off and diſcharging the water of ſprings, beſides the particular conſideration of the nature of the ſoils through which they are to be cut and formed, which is conſtantly to regulate the whole of the future operations, proceſſes, and works about them, where they are of a looſe gravelly quality, or of the nature of a quick or running ſand, the round or barrel form of drain, when turned with either common bricks or ſtones, the *lower* half being laid in mortar, and the *upper* half dry, may probably be the moſt effectual as well as the moſt durable of any that can be had recourſe to, in ſuch caſes. In moſt inſtances, alſo, of drains for carrying away wetneſſes of this kind, the outlets of them, where the water is diſcharged, ſhould be well ſecured in ſome way or other, in order to prevent any injury that might be ſuſtained by the force of the paſſing current of the water out of them.

As the common openings of the ſoughs or paſſages in theſe drains are moſtly about ſix inches ſquare, a piece of wood of that ſize, and about one yard in length, is often found very uſeful for laying in the bottoms of the drains, while forming, for building the ſtones or other materials on each of the ſides of it, and which is capable of being drawn or ſhifted forward, as the workman proceeds in completing the ſoughs or drains.

The different tools uſed in forming and cutting drains are deſcribed under their proper heads.

The making of drains of this nature, in ſome diſtricts and places is termed *ſoughing*, eſpecially when they are formed with ſome ſort of hard materials, ſuch as bricks, ſtones, or other ſimilar ſubſtances, and is a method of ſpring-draining which is very commonly had recourſe to by the drainer. See SOUGH and SPRING-*Draining*.

SPRING-*Draining*, the removing of that ſort of wetneſs in land, which is cauſed by, or which ariſes from, ſprings, in its internal or other parts, in the manner already explained under the article DRAINING *of Land*.

Its practice principally depends upon the diſcovery of the main ſprings in the different caſes, upon the proper taking of their levels, and upon making uſe of ſuch means as are capable of drawing off the water in particular inſtances, without the expence of too much cutting; as, without finding out the *main* ſpring, or cauſe of the miſchief, nothing effectual can, it is ſaid, be done; or without taking the exact level of it, and aſcertaining the *ſubterraneous* bearings which it may have; as where the drains, in ſuch caſes, are cut even a very ſmall diſtance beyond the lines of the ſprings, the water which iſſues from them can never be reached; whereas by exactly aſcertaining thoſe lines, by the practice of levelling, the ſprings can be cut off in an effectual manner, and the land be rendered dry in the leaſt expenſive and moſt eligible method. The ſuperabundant wetneſs of the land, where neceſſary, may be taken away, where the depth of the drains do not reach it, by making uſe of implements of the auger kind, ſo as to bore down, and tap or let off the water of the ſprings which lie ſtill lower.

It is conſtantly neceſſary in this, as well as other kinds of draining, to pay great attention to the direction or mode of conducting the drains, and likewiſe to the application of the tools which are employed for tapping or drawing off the ſprings. It is perhaps principally in the ſuperiority of management in theſe reſpects, that the excellence of Mr. Elkington as a drainer of land conſiſts. But though the mode of tapping ſprings by means of the auger, and letting off the water from the bottom parts of the drains, without the trouble and expence of more cutting and digging, was unqueſtionably brought to practical perfection by this able drainer, its uſe for other ſimilar purpoſes had long been known and experienced; as it has been aſſerted, that in attempting to diſcover mines by means of this tool, ſprings have been tapped, and the adjoining wet grounds, in conſequence, drained or laid dry, either by letting the water down into a porous ſubſtratum below, or giving it a vent and exit at the ſurface. The ſame tool has alſo been employed in bringing water into wells, by boring with it in the bottoms of them, to ſave the expence of more digging. This is ſuppoſed to be the caſe more eſpecially in Italy, where it is probable that the practice is of great antiquity, as Buffon has ſtated in his Natural Hiſtory, that in and about the city of Modena, whatever part is dug, when the depth of ſixty-three feet is reached, and five feet deeper bored with this tool, the water ſprings up with ſuch force, that the well is filled in a very ſhort ſpace of time. It is likewiſe noticed, that, in theſe caſes, the tool often bores through large trunks of trees, &c. which give great trouble to the workmen. This is conſequently a tool which is not only well calculated for the purpoſes of ſpring-draining, in many inſtances, but for a great variety of different other rural uſes and applications.

The porous rocky chalks are excellent conductors of water, it has been obſerved, where they have only a thin covering of an abſorbent loamy material, as they imbibe, after the ſurface-ſoil has been ſaturated, every particle of water that may come upon them in the form of rain or otherwiſe. This is ſeen to be the caſe in many hilly ſituations formed chiefly of ſuch matters, in the ſouth-weſt parts of the kingdom, as in the counties of Wilts and Dorſet. The water which is abſorbed and taken up by ſo porous a ſubſtance as chalk, it is ſaid, ſoon eſcapes the power of evaporation, and continues to deſcend, in the manner of that which paſſes through a filtering-ſtone, until it meet with an impervious or non-conducting ſtratum or layer, upon which it collects; and if this ſurface, on which it is collected, ſhould lie above the level of the ſea, or other collection of water, it forces its way out, in the manner of a ſpring, or more copious fountain; not always in one conſtant ſtream, but often periodically: the ſprings of chalk-hills differing, in this reſpect, from thoſe of the more open conducting kinds; which is a fact, it is thought, that is entitled to be more fully and philoſophically inveſtigated. The action or operation of the waters of chalk-hills, it is ſuggeſted, is moſt clearly ſeen on the ſea-coaſts, where the baſes of the chalk-cliffs reſt upon an impervious or non-conducting ſtratum or bed, which being ſoftened and worn away by the impreſſion of the waters collected upon it, the cliffs are undermined, and the faces of them thrown down. Where the baſe of the chalk dips beneath the ſurface of the ſea in low tides, the whole collection of water regains its "native home," it is ſaid, unſeen. And it is not doubted but that much rain-water, paſſing through other ſtrata, finds its way to the ſea in a ſomewhat ſimilar manner.

Rocks of the open kind, it is ſuppoſed, when they are examined as conductors of ſubterraneous water, will be found to have various effects in producing the neceſſity of this ſort of draining, according as there may be a difference in their natural properties. Sand-rock, where it is preſent, always acts, in the manner of chalk and looſe ſand, as a filter, letting the water freely through it. There are many different parts of the kingdom in which it is found in conſiderable quantity and extent, the ſurface-ſoil being moſtly dry in quality. Where the rock is of the nature of ſlate, from being of an argillaceous or clayey quality, it is often in a high degree impermeable to water; but as it in general abounds with cracks, fiſſures, and ſtill finer crevices, eſpecially near the ſurface, water readily finds its way into it, and either filtrates or percolates ſlowly through it, or finds a vent and exit in the clefts or ſeparations of the maſſes; and, collecting in ſuch parts, forces its way to the ſurface, as a ſpring; or continues to deſcend, until it meet with a more compact ſtratum, which dips towards the face of ſome hill or ſhelving ground, where, reaching the ſurface or outer limits of the rock, it either forces its way through the ſoil, and feeds a fountain, or, if the quantity of water is too ſmall, or the thickneſs and texture of the ſoil are too powerful to permit it to eſcape in a body, ſpreads itſelf beneath the ſurface materials or thicker covering, and produces watery land. A ſhelf of ſlate-rock, under theſe circumſtances, operates, it is believed, as a ſtratum of ſand or gravel. Rocks of this nature are common to many different parts of the country, as to the counties of Devon, Cumberland, and Weſtmoreland, to Wales, and the weſtern Highlands of Scotland; being, it is imagined, peculiar to the more weſtern parts of the iſland.

Limeſtone rocks, which are moſt various in texture and arrangement of parts, are met with in many places as a ſubſtratum of ſoils. The ſoft and granulous kind, of which the Cotſwold hills may be ſaid to be compoſed, as well as thoſe which ariſe in the environs of the city of Bath, and which are found in ſome places in Yorkſhire, Northamptonſhire, and probably in ſome other parts of the kingdom, is of a porous abſorbent texture; water acting upon it as upon chalk. But the more ordinary ſort of limeſtone, which may be ſaid to be met with in almoſt every department of the kingdom, is of a more cloſe texture. It is, however, commonly either divided and parted out into large blocks, or broken into fragments, though ſometimes found diſtributed in continuous maſſes. Still more frequently, the blocks ſeem as if they had been thrown together in a fortuitous manner into their preſent ſituations, being ſeparated by irregular interſpaces, either filled with earth, or other foſſile ſubſtances, or forming open fiſſures, cracks, and chaſms of different widths; and, in a few *known* inſtances, form caves or openings of extraordinary dimenſions. This claſs of limeſtone rocks may, it is ſuppoſed, without riſk, be conſidered as the moſt free and extenſive conductor of internal waters of any in this country. There are other kinds of this ſort of rocky ſubſtrata, which have directly the contrary quality and effect in reſpect to the diſtribution of water in ſoils.

The next ſort of material, which diſplays the moſt ſimple explanation of the effects which are produced by water falling or coming upon land, is that of ſand, and eſpecially where the lands are of the deep ſandy kind, ſuch as the county of Norfolk is chiefly compoſed of; ſand, it is remarked, being of a more open and porous nature than chalk, and the hills formed by it, or the more depreſſed maſſes of it, being in general of much leſs depth than thoſe of that ſubſtance, the effect is more quickly produced. Preſently after a glut of rain, the ſprings, in theſe caſes, are ſaid to fly out. Beſides, there is another difference, which is more intereſting, it is thought, to the preſent inquiry, between the effects produced by chalk and by ſand, as conductors of rain or other water. Chalk, for the moſt part, throws it out from the ſides or at the baſes of the hills formed by it, in clear ſtreams, producing no other effect on the ſurfaces of the lands than that of forming channels of conveyance for it to the rivulets or brooks, to which the particular caſt of ſurface may incline them. The waters abſorbed or drank up by chalk-hills ſeldom occaſion, it is ſaid, any thing of the nature of upland bog, unleſs when they riſe in the area of a flat-baſed valley, or are impeded and obſtructed therein, and by ſpreading and ſtagnating over its ſurface, encourage the growth and decay of aquatic plants. On the contrary, ſand-hillocks are, it is ſaid, ſingularly productive of this baneful diſeaſe of land; owing, in part, it is ſuppoſed, to a want of uniformity in their internal ſtructures, as well as of an evenneſs of baſe, when compared with chalk hills, which generally reſt on impervious ſtrata of clay; and likewiſe owing to the openneſs of the texture of the ſandy material, which ſuffers the contained waters to ſpread out and diſtend themſelves freely in every direction.

Gravel is more porous, or conducts water ſtill more freely, than ſand; and is moſtly found in thin ſtrata or veins, but ſometimes in detached maſſes, though very rarely in extended hills. In ſome ſituations it is free from the admixture of any ſort of earthy matter. In this condition it conducts water as a pipe; or when embanked with impervious matters on every ſide, contains it as a ciſtern. When a ſtratum or layer of ſubterrene gravel, or any other free conductor, is ſupplied with, or has deſcending waters coming upon it, it either conducts them to the ſurface, leads them to a fountain, or, when the ſurface is too ſtrongly guarded to allow of their eſcape, ſtores them up, and confines them in quantity beneath the ſoil. Where the gravel is partially depoſited in veins, and the covering is thin, and of an abſorbent or porous quality, the water, wherever it approaches the ſurface, fills every pore of the ſoil, and though unable to break its way out in a ſtream, as a ſtrong ſpring, occaſionally trickles and percolates through it; thus encouraging the growth of ſuperaquatic plants; which, being too groſs and unpalatable for paſturing ſtock, fall where they have grown, and, during a ſucceſſion of ages, raiſe detached mounds of vegetable earth; partaking, like the moory baſis of ſand-hill vallies, of the nature of moraſs.

If the containing ſtratum or bed be more generally and evenly ſpread beneath the ſoil, and where this is of an abſorbent porous quality, and moreover ſo thin as to be eaſily permeable, as well as lying nearly level, a large extent of ground may, it is ſaid, be rendered worthleſs,—may become a mere moraſs, or extended bog. But if, under theſe circumſtances, the land lies with much deſcent, the lower ſide only will be much affected. Further, if the ſoil or covering, though of an abſorbent porous nature, be conjointly of a ſufficient thickneſs and texture to prevent the contained waters from riſing to the ſurface, an uniform breadth of cold weak land will be produced. Where the covering is not only thick, but impervious or non-abſorbent, ſo as to prevent the depreſſed waters from riſing to the roots or feeding fibres of field-plants, lands of a valuable quality are met with: even when in the ſtate of perennial herbage, the finer graſſes are, it is ſaid, produced; but that, owing to the coolneſs which ſubjacent waters communicate to the ſoil, in the early ſpring, vegetation is more backward, and the produce leſs than it would be, if the cauſe of the coolneſs were removed by this mode of draining. Land of this deſcription is met with extenſively, and in great abundance, on the ſlopes, and at the baſes of the riſing grounds, in almoſt every vale-diſtrict of the kingdom.

Pebbly matters, which are a common ſubſtratum of land, it is ſaid, in the more mountainous parts of the country, act in a ſimilar, but more complete manner; being a ſtill more free conductor of ſubterraneous waters than gravel.

The manner in which chalk conducts ſubterraneous water to the ſea, without injury to the ſurface of the land, is ſeen above; and open rock, ſand, gravel, or any other porous or conducting material, either ſingly or in conjunction, have the ſame effect, when they form a free and continued connection between it and the ſurface of the open abſorbent lands. But the ſame ſubſtructure, when ſituated at a diſtance from the ſhore, and cut off from all ſubterrene communication with the ſea or other waters, by the intervention of impervious or repellent matters, produces widely different effects; and is capable of doing much miſchief to the lower lands which more immediately inveſt it, as well as to thoſe cloſe around it. In theſe circumſtances, the ſubſiding waters, unable to find a paſſage downwards, fill every fiſſure, crevice, and pore; continuing to collect, until the ſurface of the embodied waters reaches ſome friendly porous ſtratum, to conduct the overflow horizontally towards ſome open outlet; or until the collection has gained a ſufficient aſcendency and weight to break its bounds, and force its way to the ſurface, or blend with the ſuperficial waters. The bottom of a lake, or the channel of a deep-ſunk river, firſt offers the means of relief, in many caſes; and it is not unuſual to ſee ſpring-waters curling at the ſurface of a deep river-pool. In many ſituations, it is ſuppoſed probable that rivers receive larger ſupplies from their own beds than is evident to the eye of common obſervation. Where the river-bed is ſhut againſt them, the impounded waters naturally continue to riſe, until they reach an open ſtratum of the lands on its banks, and thus effect their eſcape. Where no ſuch conducting ſtratum offers itſelf, deep cleft dingles and narrow dells, branching out of the rivered valley, or wider vale, may, it is ſaid, be conſidered as the next places calculated for giving vent to riſing waters: and here they are not uncommonly found boiling up through beds of ſand or gravel, or the ſhattered fragments of rock; and by ſpreading, in a ſtate of nature, over the baſe of the dell, give riſe to moory grounds; or iſſuing from its banks, give birth to a more active ſtream. No deep ſunk dell occurring, or any abſorbent ſtratum of the vale lands being ready to receive the internal waters, or, having received them, being unable to give them vent, by reaſon of their being cloſed on their lower margin or border, the ſurface of the embodied waters neceſſarily continue to riſe above the baſe of the hill, until, having reached a proper conductor, a ſpring or fountain is formed; or meeting with a deſcending ſubſtratum of abſorbent or porous matter, it enters it with the effect of deſcending waters, and produces different ſorts of wetneſs according to circumſtances. On extenſive continents, and even in the interior parts of this iſland, inſtances of a ſimilar nature muſt neceſſarily, it is ſaid, frequently occur.

It may be alſo noticed, that it muſt likewiſe not unfrequently happen, that waters which have been abſorbed by the porous materials of high lands are checked in their deſcent, before they reach the baſe of the hill or mountain which has imbibed them; in the interior of which, it is more than probable, minor reſervoirs are formed by riſing waters, and there act in a ſimilar manner to thoſe which are formed at a greater depth. The perpetual ſprings which may be ſaid to be every where iſſuing from the ſides of hills, are ſtrong evidences, it is thought, in favour of ſuch a poſition. For what, it is aſked, but an extended ſurface of embodied waters, could ſend forth theſe *conſtant*, and, in ſome inſtances, almoſt *uniform* ſtreams? A lake, it is well known, thus regulates the ſtream which flows from it. But to produce this effect, it is not requiſite, it is ſuppoſed, that the lake ſhould be formed in the interior of a mountain. It matters not what the receptacle is, provided it be of ſufficient extent, and its ſeveral parts, if anomalous, have a free communication with each other; whether it be a cave, an extended ſeries of fiſſured rocks, or an extenſive ſtratum of gravel, or any other freely conducting material, the ſurface of the water will be equally level, and equally capable of regulating the ſupplies received, ſo as to diſcharge an uniform or a moderated ſtream; as the wide naked waters do, which are ſeen to ſpread on the ſurface in mountain ſituations. A ſudden ſhower does not ſenſibly affect, it is ſaid, the overflow of a lake, nor does a heavy fall of rain cauſe a ſudden flood; as it does where there is no ſuch extent of ſurface to regulate the ſupply: nevertheleſs, after much rain, and ſtill more after a long continued wet ſeaſon, the overflow is increaſed, and the ſtream enlarged. And preciſely ſo, it is ſaid, are theſe ſorts of ſprings or fountains affected.

The marles which abound in calcareous matter are moſtly of an open, porous, and abſorbent nature, and not unfrequently form the ſubſtrata of lands in different places, which may receive and hold water, in ſome caſes ſo as to let it break out and produce ſprings on the ſurface, which are highly injurious to the ſoils. Some marles are, however, of an impervious and retentive quality.

There are alſo ſome ſorts of materials which are highly impervious under ſome circumſtances, but which become porous or open in others, as clay in certain ſtates; this, however, has little to do with the nature of ſpring-draining. See Draining *of Land*.

In laying down the general principles and theory of draining land under its proper head, the manner in which the principal agents and cauſes which operate in the production of ſprings are capable of producing ſuch effects in different circumſtances, has been particularly explained, though the great internal ſprings which ſupply the interſecting rivers of countries have not been touched upon, as they have not yet been by any means ſufficiently inveſtigated or explored; and beſides, they moſtly lie at ſuch great depths, as not to affect the ſurface, conſequently have nothing, or very little, to do with the preſent inquiry.

Draining, on the principle of removing ſprings, not only produces extraordinary effects in the laying of the lands dry which are near to them; but in cauſing ſprings, in wells, wet grounds, and other places, at very conſiderable diſtances, to become dry, though they had no evident communication or connection.

Drainage of Boggy, Moraſſy, Swampy, and other wet Land, produced by Springs.—See Bog and Draining *of Land*, under which articles this ſubject is diſcuſſed as far as our limits will allow.

A pump has been lately contrived by Mr. Wakefield, the ingenious drainer of Trafford and other moſſes in Lancaſhire, for aſcertaining the lines of ſprings in this ſort of draining, which is ſaid to anſwer well. See Spring-*Draining Pump*.

In many caſes of this ſort, it may be known, it is ſaid, whether the channel of the water lie deep or not, by the appearance of the ſurface. Where the land is dry immediately above the place where the water ſprings up, it is an evidence that the channel or reſervoir lies deep, and that the water is forced up ſo as to iſſue in a perpendicular manner; but, on the contrary, where the land is wet for ſome diſtance above the principal outlet of the ſpring, it is a ſure ſign that the water is flowing in a channel near the ſurface, and that the *overflowings* of it cauſe this wetneſs. It will be a certain evidence of this, if there be only one ſpring in the wet ground; but if the internal ſtrata do not lie horizontally, or regularly, and ſeveral ſprings appear, ariſing from water running in different channels, the land above the largeſt or principal ſpring may be wet, not from the *backing-up* of that ſpring, or its channel being near the ſurface, but by the breaking out of the leſſer ſprings in their *deſcent*, the channel of the waters of which has thus found a vent and exit to and out of the ſurface, higher than that of the larger ſpring. It is in caſes of this kind that draining is attended with moſt difficulty; and where all the cutting and other matters neceſſary cannot be ſo eaſily aſcertained at firſt, until ſuch time as what is abſolutely requiſite be executed, which will lead to the diſcovery of what further is wanted, and in what manner it ſhould be accompliſhed, by expoſing to view the ſubſoil, or under ſtrata, in which the water flows. The making of *exploratory bores* with the auger, is, it is ſaid, uſeful in this and all other difficult caſes.

Where, in ſuch caſes as the above, there are different lines of drains cut one below another, from the highermoſt ſprings between the wet and dry land, not of ſuch depth as to catch and intercept the water all the way down the ſlope, as formerly practiſed, however they may be filled with looſe ſtones, though they may render the ſurface drier while they continue to run, they ſoon choak up, and burſting out in different parts, the land ſoon becomes equally, if not more wet, than it was before they were made, and ſo formed out. It is more difficult to drain this ground a ſecond time, even in the proper manner; as the ſurface, by means of the former drains, being ſo much altered from its natural appearance, the true ſituation of the ſprings cannot ſo eaſily be hit upon, and the frequent burſts of the old drains increaſe the perplexity in no ſmall degree. It frequently happens that the uppermoſt, where they are the *ſtrongeſt* outlets, are the *main* ſprings, and thoſe below only *leakages;* which implies, that ſome of the water from the main ſpring finds a paſſage through ſome opening in the *upper ſoil*, near the ſurface, and breaks out lower than the main ſpring, when it meets with reſiſtance from any bed of clay: by cutting off the main ſpring, this of courſe becomes dry; therefore the ſame caution is neceſſary to aſcertain this before proceeding to mark out the drain or drains in ſuch caſes, as from the *main ſpring only* the level muſt be taken. In irregular banks, where the ground, owing to the perpendicular ſituation or preſſure of water behind, has *ſlipt*, or fallen down, the drain muſt be carried higher up the declivity than where the water has its apparent outlet, to the ſound ground that has undergone no change, and where the *real* ſpring will be intercepted; the water in the ſlipt ſand below being only leakages from that above, but which is apt to deceive in cutting the upright trench, or that which is made from the outlet up to the croſs one, along the line of the ſprings. When the main ſpring riſes in a ſteep bank a conſiderable height above the level of the brook or place where the drain is to diſcharge itſelf, it is unneceſſary to cut a deep trench, or to lay a covered drain, all the way from the brook up to it; for the deſcent being too rapid, and if deep cut by croſſing veins of ſand, that are always met with in ſuch ſituations, the bricks or ſtones with which the *ſough* or conduit of the drain is laid, would be undermined by the rapidity of the current, which would alſo carry down a great quantity of the looſe ſand; but it ſhould be begun only ſo far down the bank, as, by *cutting in level*, the drain may be ſix or ſeven feet lower than the outlet of the ſpring, or whatever depth is neceſſary for drawing down the water to ſuch a level as it may diſcharge itſelf without riſing to the ſurface, or injuring the ground adjoining it. The remaining part of the cut, down to the brook, either in a ſtraight or ſloping direction, may be left open, and need not be deep, but guarded from the cattle, and from the plough when the field is in tillage. If covered, it need not be deeper than two feet; and there is no occaſion for boring in any part of it.

When there may be any difficulty in aſcertaining the exact line of the ſpring and that of the croſs-drain, where *it* does not *appear* on the *ſurface*, or when there is no apparent outlet from whence to take the level, in bringing up the leading drain for carrying off the water, it can be then diſcovered when it croſſes the proper line, and without cutting any farther up, the croſs-drain muſt be carried on that level, ſo far to each ſide, along the *tail* or termination of the rock or ſand containing the water, as the ſituation of the ground and other circumſtances may require. And if, in cutting the croſs-drain, the line marked out by the ſpirit-level ſhould be found in ſome places to be below that of the ſprings; and if in boring along that line no water be found, then ſmall cuts muſt be made, of the ſame depth, from the drain up to where the ſpring lies; for if the drain be cut *below* the line of the ſpring, all poſſibility of reaching it, even by the auger, is loſt, as boring can have no effect where the ſubſtratum is clay, and where there is no *under* water; and if it be cut *above* the line of the ſpring, it will require deeper cutting and boring to reach it, as there, for the moſt part, the ground riſes higher, and that part of the porous ſtrata below the drain may contain as much water as may injure the ground, and which may eaſily paſs under the bottom of the trench, between the auger-holes, and find vent below it. If the expanſe of the valley or bog betwixt two banks be ſo narrow, that the ſtratum of rock or ſand containing the ſprings, unites within reach of the auger below the clay, one trench up the middle, with auger-holes, will do the buſineſs, without any croſs or branch-drains. Although the ſprings that injure ground in this ſituation break out of the banks all round nearly on the ſame level, yet the reſervoir from whence they proceed may, it is ſaid, be hit on in the middle of the valley, by boring through the ſuperincumbent body of clay that forces the water to riſe and ooze out along the upper edge of it, at its junction with the higher porous ground. The drain being cut in the hollow part of the ground, and the ſpring below bored into, it is evident that the depth of the drain being ſo much lower than the natural outlet of the ſprings, the preſſure of water above that level, which is the bottom of the drain, will force that under the trench through the auger-holes; or even for ſome time, until the water ſubſide, it might be made to riſe higher than the level of its natural outlet. The conſequence of this will be, it is further ſaid, that the water of the ſpring having found, by means of the drain and boring, a new and eaſier channel, will ſoon abandon its former outlets, and ceaſe to overflow the ground that formerly lay below it. Many remarkable inſtances of this ſort of drainages are ſtated to have been performed by Mr. Elkington in different places, and particularly at Scariſbrick-Hall, near Ormſkirk, in Lancaſhire.

However, bogs, or wet grounds of the ſame nature in ſimilar ſituations, may, it is ſuppoſed, proceed from different cauſes, and, of courſe, require different ſorts of treatment in the removal of their wetneſſes. In ſuch caſes, the firſt thing to be conſidered, in examining the ground, is, whether the ſprings proceed from one ſide only, from both ſides, or lie in the middle of ſuch bogs; as, according to the nature of theſe circumſtances, the line or lines of the drain or drains muſt be directed. In order to properly aſcertain this, it will be neceſſary to have recourſe to the uſe of the ſpirit-level. If the bog ſhould have a deſcent from one ſide to the other, although the wetneſs may appear all round, it will be evident that the water proceeds only from the higher ſide, but paſſing over and under the ſurface, part of it is abſorbed by the dry ground along the lower ſide; from whence, if the level were not previouſly aſcertained, it might be ſuppoſed alſo to proceed. In this caſe, one drain cut along the upper ſide will be ſufficient to keep it dry. If the bog ſhould have a deſcent from both ſides to the middle, or be perfectly level, the ſprings may proceed from both ſides; and will, conſequently, require a drain on each, if they do not unite in the ſame ſtratum below the middle of the bog, and can be hit on by boring in one drain cut in the centre, as already ſhewn.

In caſe a bog of this nature between two hills is of great extent, it may be requiſite to have three different drains; one on each ſide, and one in the middle; which laſt muſt be an open one, to receive the whole of the ſurface-water, as well as to cut off any ſprings that may ariſe in that part of the bog. In all caſes of this nature, where there is any difficulty of diſcovering from whence the principal ſprings proceed, or what is the nature and inclination or diſpoſition of the ſubſtrata, the application of the auger may be had recourſe to for the purpoſe.

But in very wet ſwamps, or bogs of great extent, it is neceſſary to have other cuts than thoſe that carry off the ſprings: for although the upper ſprings, which are the principal cauſe, be cut off, there may be veins of ſand or gravel lower than thoſe, out of which it is alſo neceſſary to extract the water. If the ground is to be divided into incloſures, the open ditches may be ſo directed as to hit on theſe lower collections of ſubjacent water, as well as to carry off any that might ſtagnate in the hollow parts of the ſurface. The next thing to be conſidered in this ſort of draining is the conducting of the drain, after the levels have been taken, and the true line of it fixed; and whether it ſhould be covered or open. If the land is to be incloſed, and as the line of the trench may ſerve as a proper diviſion of the ground, it may be made an open cut, or ſunk fence; if not, a covered drain: but it is firſt neceſſary to aſcertain which, as the depth, width, and other circumſtances, may be regulated accordingly. After finding the neareſt outlet, where the water collected in the drain can be diſcharged, from that a trench muſt be brought up to the croſs one that is to be carried along the line of the ſpring, allowing a ſmall declivity of a few inches in every ten yards, for the water to run. In cutting the drain that is to carry off the ſpring, if, after paſſing the clay, there be a ſtratum of hard gravel betwixt that and the ſand containing the water, it is preferable to lay the *ſough* there, being a more ſolid foundation for it, and either to perforate the gravel with the *punch*, or open ſmall pits through it with the ſpade; by means of which the water will flow up, and run as ſpeedily off, and with more ſafety, than if the ſough had been laid in the ſand itſelf; which would not only increaſe the depth and difficulty of working it, but in many caſes the level of the orifice will not admit of the drains being cut to ſuch depth. Alſo, if, in cutting the trench along the tail of the rock, the level of the orifice will not admit of its being cut ſo deep as to touch the rock, the clay or impervious ſtratum that lies immediately above it muſt be bored through, when the water will flow up through the fiſſures of the ſtone, and through the auger-holes, into the ſough; but it is preferable, in caſes where the level will admit, to dig the drain through the clay, and ſo far into the rock as will furniſh ſtones for laying the ſough; and then the water will meet with leſs reſiſtance, and have a freer iſſue, than if the ſtone had not been opened or broken. This will increaſe the expence of cutting the drain, but leſſen that of quarrying the ſtones elſewhere, and of carrying them to the place where the drain is made. Although in the ground to be drained there may be a ditch, or other old water-courſe, in which it may be practicable, by means of boring, to *tap* the ſpring, yet it is better to make a new trench, in which the water of the ſpring only can have admittance; and where this muſt croſs any ditch or old water-courſe, it muſt be ſecured by *puddling* with clay, or be conveyed in a *wooden trough*, ſo as not to receive any ſurface-water: which, by being augmented in time of floods, might ſoon blow up and deſtroy the ſough. As the water thus obtained by means of boring may be converted to ſeveral uſeful purpoſes, as thoſe of irrigation, ſerving ſmall mills, canals, houſes, fiſh-ponds, paſtures, fields, &c. caution is neceſſary in uſing the auger, leſt the water procured in one part of the drain may be loſt at another, in the ſame manner in which it was found; and, in the endeavouring to procure a greater ſupply, it may by that means be let *down* from a *wet*, into a *dry, porous ſubſtratum,* as will be ſeen in its proper place.

Such are the chief objects that require conſideration before beginning to cut the drains: the following directions will be uſeful in guiding the execution of them. If the drain is to be cut through a ſoft boggy ſoil, it is better to be open than covered, eſpecially where it may receive other water than that collected from below, and can at the ſame time ſerve as the ſide of an incloſure or diviſion betwixt the upland and low grounds. Stones laid in ſuch drains are ſoon apt to ſink, owing to the ſoftneſs of the bottom, and the ſough may alſo be ſoon choaked up. The width of a covered drain may be from three to four feet at top, and one and a half or two feet wide at bottom, thus allowing ſix or nine inches for each ſide-ſtone, and ſix inches between, for the paſſage of the water, forming a ſquare conduit, or what is termed the ſough, being alſo ſix or nine inches in height. Or, when the quantity of water collected, or to be conveyed in the drain, is ſmall, it may only be coupled at the bottom. This is a conſiderable ſaving, both in materials and labour, requiring much fewer ſtones, and a great deal leſs time in laying them. It is equally ſecure when the bottom is ſolid, the ſtones good and properly laid, being well packed at the ſides, to prevent them from ſhifting. It is alſo a ſaving in cutting the drain, as it requires leſs width at the bottom for this manner of laying the ſtones, than it does for a ſquare conduit. In moſt caſes, however, where circumſtances are favourable, the other method ſhould be preferred. The depth is regulated by the level of the place where the drain is to empty itſelf, and the nature of the ground through which it is cut, which is commonly four or five feet, and never leſs than three. Where the drain is only to act as a conductor for the water which is brought up by the borer where the ſoil is *all* clay, its depth may only be three feet, which will be ſufficient to allow a proper depth of earth above the ſtones laid for the conduit at bottom, which need not exceed, nor ſhould ever be leſs than one and a half or two feet. Drains are ſometimes ſeen, in ground apparently very wet on the ſurface, cut to the depth of three and even four feet, and ſeveral hundred feet in length, without any water being collected by them; but when the borer has been applied, and holes put down at the diſtance of ſix yards apart, and eight or ten feet deep, a conſiderable ſtream of water has been procured, and which has continued to flow. In a particular inſtance, a drain has been directed to be cut in a very retentive clayey ſoil, which, at the depth of four feet, met with no water; which gave occaſion to the workmen to ſay, and the proprietor to think, that he was laying out his money to very bad account; but they were ſoon convinced to the contrary. As the drain had a ſmooth and uniform ſlope in the bottom, in order to expedite the work, ſeveral men were employed to lay the ſtones, beginning at the *lower* end, and proceeding upwards, while others were engaged in boring at the *upper* end, to proceed downwards. When thoſe below began their work, the drain was quite dry, and had no appearance of water, either from the ſides or bottom; but by the time they had proceeded a few yards, and two or three holes were made above, an unexpected ſtream of water made its appearance, to their no ſmall aſtoniſhment; and which has ſince had the effect of laying dry a piece of very wet land. This fully ſhews, that without the uſe of the auger in ſimilar caſes, many drains may be cut to an extenſive depth, without effecting the deſired end, or without making any material change in the appearance of the land.

In ſoft boggy ſoils it is often neceſſary, where the drain is to be covered, to cut to a much greater depth than in other caſes, or to the bottom of the moſs, in order to have a ſecure foundation for the ſtones, as a great part of the water is conſtantly lodged between the moſs and the next ſtratum. In digging the drain, it is beſt to cut the whole length to the depth of two or three feet, at which there is no danger of its falling in; and when the ground near it by that means has become more firm, and the ſtones have been laid down by the ſide of it, then cut to the depth required. In this way the ſtones are at hand, and ready to lay ſo ſoon as the proper depth is dug, and the laying ſhould be begun at the upper ſide, proceeding downwards, ſmoothing and clearing the bottom of the drain. By this means, the fall of the water will be ſeen and kept, as there is a danger, when the work is begun at the lower end, and laying upwards, in level ground, of digging too deep in clearing the bottom, and thereby cauſing a ſtagnation of water and ſludge in the ſough, which ought to be carefully avoided. The turf, in opening the drain, ſhould be firſt pared off thin, and laid to one ſide for after uſe, and all the mould thrown out to the other. The moſt difficult part of the work is laying the ſough in running ſands, where it is neceſſary to have the ſides of the trench ſupported with flat boards and props, which are removed forwards as they proceed in working, and which keep the ſides from falling in, and the looſe ſand from falling amongſt the ſtones with which the conduit is laid. If the ſough or conduit be laid with brick, a ſmall aperture muſt be left betwixt each, to admit the water from the ſides of the drain, and the thin turves muſt be laid above, graſs-ſide downwards, to prevent the mould from getting through the openings. The turves are laid graſs-ſide downwards, *immediately* above the *ſtones*, without any looſe ſtones above the laid ones, as the water is all collected from the bottom of the drain, very little from the ſides of it, and none admitted from the top; unleſs in ſuch caſes as where the ſtratum containing the water, or that may receive it in time of rains, is cut through to a greater depth than the height of the conduit, then ſmall ſtones muſt be laid above the conduit or cover ſtone, to the height of ſuch ſtratum, or as far up as the water appears to ooze out. Theſe ſmall ſtones admit the water to ſubſide through their interſtices to the conduit or ſough below, and thus prevent the bad effects that would otherwiſe proceed from its confinement ſo near the ſurface. In quick or running ſands, turves muſt alſo be laid at the bottom of the drain, under the ſough, to prevent the looſe ſand from flowing up, and to render the foundation of brick or ſtone more ſecure in caſe of their ſinking. Before boring, it is proper to lay the ſide-ſtones of the conduit; after which the holes may be put down, at the diſtance of every four or ſix yards. But if the water, on withdrawing the auger, ruſh up with violence, and continue to have a boiling appearance, it indicates a ſtrong body of water confined below, and, conſequently, requires a great number of openings to give it a ſpeedy and ſufficient vent. When the force of the water is great, the width of the holes enlarges, and conſequently the diſcharge is increaſed. By a careful examination of the adjoining ground, it is ſometimes poſſible to ſay at what depth the ſtratum containing the ſpring lies, and conſequently how deep the *bores* muſt be made; but the general rule is to go down until the water riſe immediately on withdrawing the auger. Thirty feet have been bored down before the water flowed in a full and free manner; but about from ten to fifteen feet may be ſaid to be the average depths of boring. One caſe is ſtated, in which, after boring thirty feet, the water iſſued in a quantity equal to *three* hogſheads in a minute, by which a great extent of wet ground in the vicinity was drained. In theſe ſands, it is alſo better to dig a little into the ſides of the trench, off the line of the ſough, where the auger is to be uſed, and, after boring, to cover the places in the ſame manner as the reſt of the ſough, leaving out a ſide-ſtone oppoſite the hole, as the ſand thrown up by the ſpring can thus be more eaſily taken out with the hand till it ſubſide and give over running, and is likewiſe off the main current, coming down the middle of the drain. That part of the ſough above the auger-holes ſhould be left uncovered till the ſand is all thrown up, and the openings clear; but, till then, the ſand muſt be taken out, and the ſough may afterwards be covered up with ſafety. Above ſome of the auger-holes, or at any other convenient part of the drain, a kind of funnel may be built to the top of the trench with a flat ſtone laid over it, whereby it can at any time be looked at to ſee if the iſſue is clear, and if the quantity of water diminiſhes or increaſes. When the circumference of the auger-holes is not ſufficient to let up the quantity of water which the ſprings would otherwiſe iſſue, where it is not far from the bottom of the trench to the ſtratum containing the water, and where there is a bed of hard gravel intervening, impenetrable by the auger, holes muſt be dug with the ſpade, down to the ſpring, and theſe holes filled up with looſe ſtones; firſt putting down a round ſtake in the middle, which, after the ſtones are filled in, muſt be drawn out, which leaves an opening for the water to flow up. No apprehenſion need be entertained of the holes made by the auger being filled up, whether the drain be open or covered, provided no other water is admitted; for ſuch is often the force of the ſpring, that it will throw up any earth or other ſludge that may accidentally get into it; and it can be injured only by the admiſſion of great quantities of ſurface or flood-water coming up on it at once. When flat ſtones can be got, they are preferable to brick for this uſe; but there are ſeveral kinds of brick beſides the common ſort invented and uſed only for the purpoſe of draining, in ſeveral parts of the kingdom, where the expence of ſtone would become greater. When ſmall drains are wanted, and when the water is to be conveyed to a houſe, &c. that which is of the arched form is commonly made uſe of. For larger drains, thoſe of the ſquare, hollow, pantile form are well adapted, eſpecially the latter. They are laid ſingle, without one reverſed under; for when that is done, the water running on the under one occaſions a kind of ſludge, which in time becomes ſo encruſted on it, as totally to obſtruct the paſſage of the water, and render the work uſeleſs in a few years. In clay bottoms they may be laid ſingle, or without any thing under; but in ſoft ſandy bottoms, a common building brick ſhould be laid under each ſide to prevent them from ſinking down, and be ſo laid as to form a regular arch, by the ſide-bricks being laid with an equal height, the better to ſupport the preſſure above from breaking them. They may be conſtructed in the above ſhape to any dimenſions, ſuitable to the quantity of water the drain is to convey.

Although the earth that is thrown out of the drain ſhould, when filled in again, be conſiderably higher than the ſurface of the ground on each ſide, it muſt remain ſo; for in a year or two it will ſubſide to the level of the ſurface on each ſide. What remains may be ſpread or laid in ſome adjoining hollow; for, if levelled at firſt, the earth immediately above the drain ſinks down, and the rain by that means lodging in the hollow and ſubſiding downwards, may injure the ſough, by carrying part of the ſurface of the earth along with it.

While the drain is cutting, in very wet peaty ſoils, the ſurface-water, or what may ooze from the ſides before coming to the ſpring, muſt be ſtopped here and there; and when let out to run through the ſough, a turf or bunch of graſs muſt be laid ſo as to prevent any ſludge which it may bring down from running through along with it, as this might choak the laid part of the drain and ſtop the paſſage of the water. When trees, eſpecially aſh, happen to be in the courſe of the drain, they muſt be entirely *grubbed* up, otherwiſe the roots will get into the ſough, and expanding through the joints of the ſtones, will ſoon put a ſtop to the paſſage of the water. When the water iſſued by the drain becomes of a red *ochrey* colour, it indicates a ſtagnation either from the above cauſe, if amongſt planting, or from ſome part of the ſough having fallen in; which ſhould be ſpeedily repaired, otherwiſe the grounds will ſoon become equally wet as before. In the laſt place, the mouth of the drain ſhould be carefully railed in, or otherwiſe guarded, to prevent the cattle from trampling it or choaking it up, being fond of drinking there for the ſake of the cool water, even although there be watering-places in the field; and where there is any defect of this kind, it ſhould immediately be remedied. Likewiſe the outlets of the drains where they empty themſelves into an open ditch, or run of water, ſhould be often examined and kept clear, as they are very apt to be choaked up with graſs and ſand when neglected in ſuch places. The firſt ſymptoms of the drain's having effect, and which ſoon appear when the ſpring is properly *tapped*, are, that all the *ſurface-drains* that may have formerly been made, and alſo any adjacent pits, ditches, or places to which it may have *backed up*, immediately become dry, and remain ſo afterwards. On the whole, it appears from the foregoing obſervations, that this mode of draining bogs, or land injured by ſubterraneous water, is by far the moſt effectual of any that has yet been ſuggeſted; and that ſuch ground may be made completely dry, by *cutting* off *one* ſpring alone, with which the particular place to be drained may have no apparent communication, but which may be ſo connected *under* ground, that from it all the others derive their ſource, and being therefore the *principal* cauſe of the whole, to *hit* on it ſeems the chief deſideratum of the buſineſs. Many inſtances of this have occurred in the practice of draining boggy land, under the direction of the above expert drainer, where by a few auger-holes, hitting upon the particular ſpot where the *loweſt* part of the *main* ſpring lay, a conſiderable extent of ground, with which the drain had ſeemingly little connection, has been laid dry, and cauſed much ſurpriſe to thoſe who witneſſed the effect. At Odſtone Hall, in Leiceſterſhire, a conſiderable tract of wet marſhy ground, of very little value, divided in the middle by a ſmall river, was ſo completely drained, it is ſaid, by the ſame experienced drainer, by making a ſmall trench at one ſide, and by boring in it, that the part of the marſh on the oppoſite ſide of the rivulet, which was at a very conſiderable diſtance from the drain, became, in a ſhort time, equally dry with that where the cut was made; has continued ſo ever ſince; and, from being formerly of little or no value, is now converted into excellent *water* meadow, producing, *without* manure, abundant crops of graſs and herbage.

At Madeley alſo, near the town of Newcaſtle, in Staffordſhire, there was likewiſe a very conſiderable bog of ſome hundred acres, the drainage of which was deemed impracticable, being of ſo wet and ſoft a nature that no cattle could paſs over any part of it, until this able drainer lately obtained a leaſe of it for a certain number of years, and, by means of a very little cutting and expence, has in conſequence ſo effectually drained it, that it may now be conſidered as not only a ſingular inſtance of the ſucceſs of this ſort of draining, but as being likely ſoon to become highly productive as a farm, in conſequence of other improvements, which this has produced, on it.

Extenſive bogs too, which were formerly conſidered as incapable of being reclaimed, have within theſe few years been effectually laid dry, by this ſort of drainage, at or near Woburn, belonging to the noble duke who reſides near that town, at but very little expence, conſidering the manner and nature of the undertaking in ſuch bogs. The drainage, in theſe caſes, was accompliſhed by the ſame ſkilful drainer.

Succeſsful drainages of this kind have alſo been performed in different parts of the northern diſtrict of the iſland: and particularly in the extenſive park of the duke of Buccleuch, where the work has been carried on in exactly the ſame manner, and in perfect conformity to the principles, and the rules and directions which have been laid down for the drainage of the firſt claſs of theſe ſpring-bogs. In this caſe, the ground has not only been rendered dry and much more valuable than formerly, but the drains have likewiſe ſerved the uſeful purpoſe of affording a conſtant ſupply of ſpring-water to different parts of the park.

It has been ſuggeſted by the writer of the Middleſex corrected Agricultural Report, that, wherever there may be any bogs, draining is unqueſtionably the firſt ſtep to be taken towards their improvement; for the accompliſhment of which, the principles and practices which have been laid down above ſhould be reſorted to, though the drainer ſhould not be too ſanguine, or imagine that it is, in every caſe, an eaſy operation. It is much feared, that there are *ſome* bogs which could not, without great difficulty, be drained at all; and *others*, that would coſt the value of the land, in drains and machinery, to fully effect it. Yet, notwithſtanding ſome *unſucceſsful* trials may have been made, they ſhould, it is ſaid, not diſcourage or prevent the making of ſuch attempts, in all caſes, where there is tolerable proſpect of ſucceeding in them. The inſtances are, no doubt, very numerous, it is thought, in which this ſort of land may be effectually drained at an eaſy expence; and thereby be brought from a ſtate of *annoyance* to yield conſiderable *profit* to the owners, as well as the community. See Bog, Morass, &c.

Drainage of Ground on the Sides of Rivers, and flat ſwampy Land, below the Level of artificial Leads or Runs of Water.— It is alſo ſtated, that many extenſive tracts of land are wet and ruſhy, from a cauſe that cannot be removed by any number of open or covered drains. This is called *haugh* or holm-land, and lies along the ſides of brooks and rivers, which having altered their courſe ſo often between the oppoſite banks, and depoſiting ſand and gravel as they recede from their laſt channel, the water of the river conſtantly percolates through the ground thus formed to the level of *its* preſent courſe, keeping it ſo moiſt and wet as to produce ruſhes and other coarſe aquatics; and wherever a drain or pit is dug in ſuch ground, it immediately fills with water to the level of that in the river. Where the river has a quick deſcent, it is leſs apt to produce this effect; but where the current of it is ſlow, and the level of its ſurface little below that of the ground on either ſide, the ſoil will be very much ſaturated with water. Any number of drains cut in any direction, can have no good effect while the river continues in its preſent courſe at ſuch a height. Conſequently the only remedy, where it can be had recourſe to at a moderate expence, is, it is ſuppoſed, deepening and widening the bed of the river, the earth taken out of which will, at the ſame time, ſerve to form an embankment on either ſide; for while it can riſe higher than the outlets of the drains, and flow back into them, it renders the ground equally wet as before they were made, and the expence of making them is laid out to no advantage. Beſides being injured in this way by the *river*-water, ſprings, in many ſituations, iſſue from the bottom of the higher banks or ground, and ooze through the ſoil higher than *its* level. The water of theſe can eaſily be cut off or lowered to the level of the river by a proper drain, as will be afterwards ſeen. As this ſort of land is moſtly formed by the rivers changing their courſes, and thereby leaving conſiderable extents of flat level ground on one or both ſides of them, which is of an alluvial nature, and commonly of a very rich quality, being for the moſt part conſtituted of very fine earthy particles, which are either depoſited by the water in the time of or after floods, or waſhed down from the higher grounds in time of heavy rains, and ſometimes by both; its drainage and embankment muſt conſequently, when neceſſary and practicable, or capable of being performed without any extraordinary expence, be highly deſirable and important. See Haugh-*Land*.

But in ſome caſes the wetneſs proceeds entirely from ſprings, where the ſoil of the flat ground betwixt them and the river does not conſiſt of looſe gravel or ſand, but of a loam or clayey mixture. In order to drain this ground, a trench muſt be begun at the lower end of it, and brought from the river along the bottom of the bank from whence the ſprings iſſue. This trench ſhould be cut *below* the line of the ſprings, where it can more eaſily be done, and kept open to receive the river-water in floods, and alſo any runs of water from the high grounds in time of rains, which would *blow it up* if covered; and muſt diſcharge itſelf into the river at the loweſt poſſible level. Where the ground by the ſide of the river is of ſuch extent as to render a regular embankment along the ſide of it a matter of conſideration, a flood-gate might, it is ſuppoſed, be placed at the mouth of the outlet-drain, which would ſhut with the preſſure of the river-water in a flood, and thereby exclude it entirely from the inner ground, and would open by that of the water accumulated in the drain during the inundation, and ſo be emptied into the river when it ſubſides. The conſtruction of ſuch a gate is ſimple, and the only remedy in caſes where it is deſirable to have the flood-water excluded in ſuch inſtances.

From this trench, ſhort covered drains muſt be cut up a little way into the bank, to lead in the ſprings that are above it, where boring oppoſite to them has not that effect. The bottom of theſe muſt be higher than the level of that of the open cut, to prevent any of the water in it from flowing back into them. In theſe the auger muſt alſo be uſed to *tap* the ſprings, if the depth of this level does not reach the ſtratum containing the water. There will be no occaſion for any croſs-drains betwixt the open cut and the river, as all the water that is intercepted will be carried along the bottom of the bank, and emptied into the river at a lower level, unleſs the ground be of ſuch extent that it may be divided by croſs-ditches into ſeparate incloſures. The open drain along the upper ſide will ſerve as a diviſion betwixt the meadow and higher ground.

This ſort of land, from its peculiar ſituation, and the nature of the ſoil, is moſtly well adapted to the purpoſe of being watered after it has undergone proper drainage.

In caſes where a mill-lead, or other ſimilar artificial runs of water paſs through land, there are many valuable tracts which are not unfrequently conſidered as impracticable in their drainage. Alſo where they glide along the ſides of them to which the falls incline. From the low ſituation of the ground in ſuch circumſtances, and the height of the water in the leads or runs, there is no fall for diſcharging into them the water of any ſuch drains as may be cut to the neceſſary depth. The only expedient for the remedying of this difficulty is ſuppoſed to be the following, which has been had recourſe to in different inſtances, where no other mode was practicable, with the moſt complete ſucceſs. In all ſuch caſes, the firſt thing is to begin, it is ſaid, at the river or natural ſtream, and bring up a cut to the lead or run at the point where the outlet of the upper drain is to croſs it. This cut muſt be as deep as the river will permit, or the drains above require. A cut muſt then be made acroſs the lead or run to the ſame depth, and a ſtrong wooden trough, or ſquare box, for which larch wood is the beſt, made of a ſufficient ſize to admit the water collected above to paſs through it, be placed acroſs it. The length of this trough muſt be ſeveral feet on each ſide more than the width of the lead or run, and muſt be ſecured by ſtakes firmly driven down into the ground on each ſide, with croſs-bars or pieces above, to hold it ſecurely down. The ſpace between the top of it and the bottom of the lead or run, muſt be well filled with clay cloſely beat or rammed down. After this, the cut to the higher ſide of the ground may be made as deep as the level of the trough will allow, and continued along the upper ſide of the wet land, ſo as to cut off the ſprings that riſe in that quarter. This may either be a covered or open drain, as circumſtances may require. From the trough, alſo, an open cut ſhould be made parallel to, and along the back of, the lead or run, to receive the ſurface-water from the ground above, and from the diviſion ditches that may be neceſſary, if the ground be of great extent. The earth from this cut ſhould be laid between it and the lead or run, to ſtrengthen and ſecure the bank. In like manner, an open cut may be neceſſary along the other ſide of the lead or run, to receive the water that may ooze from it, and injure the ground between that and the river; and this ground, if extenſive, may likewiſe be divided by croſs-ditches, or ſuch as ſerve the double purpoſe of fences, on the ſides of incloſures, and drains. The croſs or diviſion ditches, in the upper part of the ground, ſhould not join the upper drain, but a ſmall ſpace be left uncut, to prevent any connection between the ſpring-water in the upper drain, eſpecially when it is covered, and that which is collected in the croſs open ditches; and which may likewiſe ſerve as a paſſage from one diviſion of the field to another. The parts of the land between the diviſion ditches are moſtly well calculated for watering, where there is a full command and ſupply of water from the leads or runs.

Something of this manner of drainage has ſucceeded, it is ſaid, in a caſe of land lying along the ſide of a river, below gently riſing ground, where the wetneſs was commonly believed to be owing to a mill-lead penning up the water above the level of the low meadow-land; after attempts to drain it, on the ſuppoſition of the wetneſs originating from ſprings riſing in the higher grounds, by cutting them off by means of a trench, had completely failed. This was lately done at Petworth by lord Egremont, according to the writer of the "Corrected Account of the State of Agriculture in the County of Suſſex." In this caſe, the water in the river was higher than the meadow-land to be drained; but there was an old ditch for carrying the water from the low meadow-land into the river, at ſuch times as when it was low. This ditch was intended to be ſtopped up in caſe of the ſucceſs of the above mode of drainage, as the trench-drain would, it was thought, ſerve the purpoſe. But on the drain or trench being cut, the effect was, that when the ditch was ſtopped up, the low meadow-land was flooded by the ſprings, as the drain did not anſwer the purpoſe of taking away the water; and when the ditch was open, the ſame meadow-land was flooded by the river. The banking of the river out at the ditch, and the building of a wind-pump to render the ditch dry, were afterwards adviſed as the only means to be taken for accompliſhing the drainage.

A different method, of ſomewhat the above kind, was, however, had recourſe to with complete ſucceſs. Upon the levels of the meadow-land, on each ſide of the river, having been taken, it was found that the meadow-ground on the oppoſite ſide was beneath the level of the meadow-land which required to be drained, and conſequently that the drainage of it could be effected by a trunk-drain laid acroſs the bed of the river; a wooden pipe was, of courſe, laid at the bottom, to receive and convey the water of the ditch, and which was carried on forward by an open drain being cut ſo as to paſs through the other meadow-land, on the oppoſite ſide of the river, which was alſo drained by the cut thus made, quite up to the bridge under which it paſſes, cloſe to the turnpike gate, fixed there by means of a pipe, and which empties itſelf into the river at the mill-head. This mode of drainage has anſwered, it is ſaid, moſt effectually, ſo that the water in the old ditch now ſtands always a foot below the ſurface of the meadow-land which was wet; and more than one hundred acres of contiguous meadow-ground have been highly improved by the new drains which have been thus made: much of it, which was a mere bog or ſwamp before this drainage of it was completed, is now, it is ſaid, converted into a fine water-meadow, and worth full three pounds the acre. Theſe grounds are, it is remarked, at any time capable of being flowed by means of ſluices made through the towing-path, which acts as an enbankment; and in the ſummer ſeaſon, if the river be too low, by freſh ſtreams which flow into it from the upper grounds; and beſides, the water can at pleaſure be drawn off by drains into the lower level, below the locks, ſometimes, when particular circumſtances render it neceſſary, by the means of culverts carried acroſs the bottom of the river. This intereſting manner of freeing ſuch low dammed up meadow-lands from the effects of the water ſo kept up in them, may be applicable in many other caſes and ſituations of a ſimilar nature.

Drainage in boggy and other wet Ground, by perforating through a retentive to a porous Sub-ſtratum.—There is a ſort of boggy and other wet land, which is moſtly cauſed in a different way than by that of ſprings, but which, as partaking in ſome degree of the nature of that kind of bogs, and being capable of having the wetneſs removed by ſuch means as are had recourſe to in ſpring-draining, may be conſidered in this place without impropriety. In many parts of the kingdom there are conſiderable tracts of land which lie waſte and uncultivated, owing to wetneſs in a particular ſituation, that might, by means of letting down the waters into a porous under-ſtratum, be eaſily drained, and rendered much more productive. The cauſe of their wetneſs proceeds not from ſprings lying under the ſurface, nor from the overflowings of any of the adjoining higher grounds, but from the accumulation of rain-water ſtagnating on a retentive body of clay, or other impervious ſubſtance, through which the water can have no deſcent; and being alſo ſurrounded with higher ground of the ſame impervious nature, the water of itſelf can have no natural outlet. Such ground, when it becomes boggy, is commonly called *land-locked* bogs. The ſituation of theſe bogs being often ſo much lower than the grounds that ſurround them, the cutting of a main drain, or conductor, through the bank, for carrying off the water collected by the ſmaller drains, would, in many caſes, be attended with an expence greater than the value of ſuch land when drained. The thickneſs of the impervious ſtratum that retains and upholds the water is often ſo great, that although the ſtrata under it be of a porous and open nature, as rock-ſand or gravel, the water can find no paſſage whereby of itſelf to deſcend through the one into the other; and, therefore, by its long ſtagnation above, all the coarſe vetegables that have, for a ſeries of years, been produced on its ſurface, and even the upper part of the ſoil itſelf, are formed into a body of peat-earth, equally ſoft and leſs productive than that of any ſpring-bog, and which is only paſſable by cattle in very dry ſeaſons, when the wind and ſun exhale part of its moiſture; and is even then inacceſſible to the plough. The drainage of theſe bogs muſt be effected in a manner different from that of thoſe above, or ſpring-bogs, the cauſe of both not being the ſame in their nature, as already ſeen. It may probably be done in the following manner at the leaſt expence. The firſt drain muſt be made in the middle or loweſt part of the ground, and into this all the others muſt lead. The number and direction of theſe muſt depend on its extent. They muſt be cut through the peat, or wet, ſpongy, upper ſoil, to the top of the clay or retentive ſub-ſtratum, which muſt be perforated by the auger, in order to give an *outlet* downwards for the water, which will be abſorbed by the porous ſtrata below. The making one large pit or well in the middle or lower part of the bog, dug through into the porous ſubſtrata, with the drains leading into it, would anſwer equally well, and would ſave boring along each of the drains: this is a method which has frequently been practiſed with ſucceſs in different diſtricts. In Hertfordſhire, according to the corrected account of the agriculture of that diſtrict, if a pit be ſunk twenty or thirty feet in depth, in the middle of a field, through the red, flinty, and impervious clay of the county, into the chalk below, when the uſual quantity of chalk is taken out, the pit-ſhaft is filled up with the flints which are collected out of the chalk and clay, and the top, or ſurface-drainage, of this part of the field, much ſhortened for ever afterwards, by making principal drains from the part of the field above the level of the top of the pit terminate therein, and the ſuperabundant moiſture will eſcape through the flints in the pit-ſhaft to the chalk below. And if a drain be carried into a limeſtone quarry, it is ſeldom neceſſary to carry it farther.

In dells or hollows of conſiderable extent, which are covered with an impervious ſtratum, and from which there is no natural drainage; ſuch, for inſtance, as the valley between Mold, the ſhire-town of Flintſhire, and the adjoining high land; a pit about four feet in diameter, and fifteen feet in depth, more or leſs, as the caſe may require, is ſunk through the impervious ſuper-ſtratum into a pervious ſtratum of gravel, and the rain-water, and that of ſome adjoining ſprings, are carried from the ſurface thereby: the pit is railed round to prevent cattle from falling into it. It is here remarked, that though in this, as well as in many other inſtances that might be given, the top-water eſcaped through the pervious ſub-ſtratum, the effect might have been directly the contrary. It is, conſequently, adviſed, that the impervious ſuper-ſtratum, in all ſuch caſes, ſhould firſt be perforated by bore-rods, as the holes made by them are eaſily ſtopped up.

Where the firſt method is had recourſe to, the drains ſhould be cut as narrow as poſſible, and, after the auger-holes have been made, ſhould be filled with looſe ſtones to within a foot and a half of the ſurface; and this vacuity may be filled up with part of the earth taken out, having a turf, graſs-ſide downwards, next the ſtones. The water and noxious moiſture, contained in the peat or upper ſoil, will be extracted by the drains, and will ſubſide through the auger-holes into the porous ſtrata below. If the ground is afterwards ploughed, care muſt be taken in forming the ridges, and giving them a proper deſcent towards the main drain, which will greatly aſſiſt the others in diſcharging any heavy falls of rain-water.

Before proceeding to drain this kind of land in the manner deſcribed, the following obſervation muſt be attended to. It ſhould be diſcovered, in the firſt place, whether the porous ſtrata immediately under the clay be dry, and will receive the water, when let down into it from above; or, being ſaturated with water itſelf, may, in place of receiving more, throw up a greater quantity to the ſurface; and thus, inſtead of remedying the evil, render it worſe. This may ſometimes be the caſe; and the ſubſtrata may contain water that makes no appearance on the ſurface, at *this* place, owing to the ſuperincumbent body of clay, but which, being connected with ſome higher ſpring, may flow up, when a vent is given to it by the auger. Thus would a greater quantity of water be brought to the ſurface, which, having no outlet through the circumjacent bank, would render the ground much more wet, and might even, in ſome ſituations, almoſt form a lake. If the ſurrounding high ground declines deeper or lower than the bog, although at ſome diſtance, by means of a ſpirit-level, and the appearance of the ſurface, the nature of the under-ſtrata may in a certain meaſure be diſcovered; and although it ſhould already contain water, a drain may be there cut to draw off that water, and alſo what is let down into it from above.

It not unfrequently happens, that ſprings, or *ſpouts*, as they are commonly termed, riſe in the middle of a field, or portion of ground at a diſtance from any ditch or open drain, into which the water may be diſcharged; ſo that a covered drain, brought from the neareſt outlet, would paſs ſo far through dry ground, as to render the expence of conducting the water from the ſpouty part greater than the injury done by it. In order to remedy this evil, it is neceſſary to begin by cutting a drain a few yards in length, or by ſinking a pit into the porous ſoil immediately between the *lower* ſide of the wet and next dry ground; and from that to bring up an upright drain to the *upper* ſide of the wet ground, from which a branch muſt be taken to both ſides, along the upper ſide of the wet, ſo far as it goes.

This upper drain will cut off the water, when it riſes to the ſurface; while the upright drain will convey it to that cut along the lower ſide of the wet ground, where the water will ſubſide into the porous ſubſoil. An eaſier method may be practiſed, where the retentive or impervious ſubſtratum is not deep, which is firſt to cut the drain along the *upper* ſide of the wet ground, and after coming to the ſtratum in which the water flows, either to bore through the retentive ſubſtratum, or cut the drain to that depth; by which means the water cut off above will be let down into the abſorbent or porous ſtratum below, and thus be got rid of more eaſily than by any other method. But if the ground be ſteep, and the ſtratum, into which the water is let down, *tails* out any where below, or lower down on the ſlope or declivity, the water will again flow out, and cauſe a ſimilar *ſpout* or wet place in the field. This, however, will ſeldom be the caſe, it is ſaid, and may eaſily be remedied, by being made perhaps near the extremity or lower ſide of the field.

It has been ſtated, that Dr. Nugent, in his Travels through Germany in 1766, has ſhewn the mode of draining marſhes in that country to be nearly on the ſame principles as thoſe explained above. The draining of marſhes is ſaid to be conducted in much the ſame manner as that of lakes; but the operation has there been ſeen performed only on what we call moor or turf-grounds. Theſe are moſt eaſily drained, by carrying trenches through thoſe grounds, when the diſpoſition of the country is ſuch that the water can be conveyed to ſome neighbouring ſtream.

In theſe caſes, the firſt thing they do is, it is ſaid, to carry a ditch to the middle of the moor in a direct line, its depth and breadth adapted to the extent and wetneſs of the ground, and thus to the ſuppoſed quantity which is to be carried off. At every ſix, eight, or ten perches, as the ground is more or leſs ſwampy, croſs-trenches on both ſides are drawn in a direct line, and communicating on both ſides with the main trench. But, in caſe of water coming from any neighbouring eminences, they dig a trench round the whole ground as a reſervoir; and this likewiſe communicates with the main trench, &c. In caſe the draining of the water into ſome natural receptacle be not practicable, at leaſt not under a very great expence, then they have recourſe to ſinking ponds or reſervoirs in ſome neighbouring bottom, and to theſe they carry all the trenches. Theſe ponds are likewiſe ſaid to be of uſe as a fiſhery; but even if the ſinking of ſuch pond be too chargeable, there ſtill remains an expedient which is of good effect, and chiefly if the moors are not too wet and marſhy. It is the nature of moors, in general, that, beneath the turf or moſs, there is a loam which hinders the moiſture from penetrating; and this, indeed, is what makes the marſh, and cauſes the luxuriant growth of the turf or moſs: but this loam or clay is only a ſtratum, and far from being of an immenſe depth; under it is generally a ſand, or ſome other ſtony or looſe ſoil. Here reaſon readily informs us, it is ſaid, that a middling moraſs may be drained by *perforating* the clay, and thus making way for the moiſture to penetrate. In order to this, a pit is dug in the deepeſt part of the moor, till they come below the obſtructing clay, and meet with ſuch a ſpongy ſtratum as, in all appearance, will be ſufficient to imbibe the moiſture of the marſh above it. Into this pit the ebbing of the moraſs is conveyed through a trench, and both the trench and pit are filled up, after the firſt drain, with large broad ſtones, ſetting them edgewiſe, ſo as to leave interſtices for carrying off the water: then ſuch ſtones are laid over breadthwiſe, and theſe covered with looſe earth, like that on the ſurface. When no ſuch ſtones are to be had, ſtrong piles are rammed down the ſides of the trench, and broad boards laid acroſs; and theſe are covered with earth to a height fit for culture. This is a matter of no great expence, the pit being as near the moraſs as the water will admit, and the trenches but ſhort; then they have a drain unperceived, which leaves the ſurface of the trenches for the plough. And in middling marſhes, or eſpecially in ſuch moors as are only wet and damp, this method, though ſometimes ſlow, never fails taking effect; and many tracts are thereby made ſerviceable to the farmer or grazier. Much land, in ſome parts of this country, has been drained in the manner here deſcribed.

It has been done with great ſucceſs, to a conſiderable extent, near Aberdeen, in Scotland, as well as in the county of Roxburgh, according to the writer of the Agricultural Report of that diſtrict, on ſuch waſte lands as might be made arable, in which, at the depth of from one to ſix feet below the ſurface, is found, it is ſaid, a large ſeam of black ſlaty or metallic ſubſtance, generally from twenty to twenty-five feet in thickneſs; and below this is diſcovered a maſs of whinſtone rock, both lying in a tolerable regular ſtraight line. The thickneſs of the whinſtone rock, it is ſuppoſed, is unknown, as it is not believed to have ever been bored into. The black ſlaty or metallic ſubſtance is commonly found ſo cloſely cemented, as it were, without chinks or fiſſures, as that it is impenetrable even to water, or any other liquid; while, on the contrary, the whinſtone rock, when come at, abounds with chinks and fiſſures, and will receive and ſwallow up any quantity of water that may be poured into its boſom. The ſurface of the earth, above the ſlaty or metallic ſubſtance, is found every where of a light, kernelly, and moſſy nature; apparently having, in the courſe of a ſeries of ages, been produced and formed from the vegetable ſubſtances which had attached themſelves to it; falling in the autumnal ſeaſons, and having no receptacle to receive the rain-water, as it falls below its ſtratum, it preſerves it on its ſurface; and in the winter months becomes ſwelled and enlarged in a conſiderable degree. In the ſpring months, when the ſun and wind abſorb it, and cauſe it to exhale, the moſs becomes of tolerable firmneſs, and produces a coarſe kind of unprofitable graſs, mixed in many places with a ſort of ſhort heather, which is of no uſe either for the rearing or feeding of ſheep or cattle.

Two portions of this ſort of waſte land, amounting to twenty acres, the one lying nearly on a level, and the other on the ſlope of a hill, were broke up in the autumn of the year 1784. The level part was gathered up in ſmall ridges, ploughing rather deeply, and making the furrows narrow; labourers being employed, after the ploughs, to remove any obſtructions that might ariſe from ſtones or roots, as well as to turn the upper rind or ſurface underneath, when not effected by the ploughs. It was then allowed to remain in that ſtate until the middle of the ſummer of 1785, being only eaten and trodden in the ſpring ſeaſon by ſheep and cattle, which were occaſionally driven about the ground for the purpoſe, the benefit of which was very great. At the above period the land was again gathered up; but finding, although the ridges were getting high, being only ſet out eight feet at firſt, the plough did not reach or get to the ſlaty ſubſtance in the hollow of the ridge, it was neceſſary to lay out the ridges to ſixteen feet. This coſt much trouble, but the plough was at laſt got down to the ſlaty ſubſtance. When the work was ſo far advanced, the next buſineſs was directed to the getting the water drawn out of the hollows of the ridges, which were at leaſt four feet below any level that could be obtained. In order to accompliſh this, a pair of bore-rods was procured, and put down the ſlaty ſubſtance, to the whinſtone rock, at ſundry places, and which effectually anſwered the purpoſe; the tops of the holes or canals being kept covered with a baſket of looſe ſtones, which was allowed to remain or to be removed at pleaſure, as the weather proved more or leſs wet.

By this means of draining, the land was found to be, in the ſpring of 1786, brought into a condition for ſowing, nearly as early as any other part of the farm; the winter rains falling through the ſoil upon the ridges into the boſom of the ſlaty ſubſtance, which was laid bare in many places, in the hollows of the ridges; the water was gently drawn off, and glided regularly into the bore-holes or canals: and the production of crops in the following years was very good.

On the contrary, the other part of this wet waſte ground, lying on the ſlope of the hill, was ploughed in thin broad furrows; uſing the ſame meaſures and precautions as in the above caſe, and being allowed to remain to the ſame period, after breaking up, was then endeavoured to be brake-harrowed, and afterwards prepared for burning. But both theſe methods failing, it was left in a more backward ſtate than the former part; and was at laſt, in the ſpring of 1786, after two ploughings, braking, &c. being left in a large lumpy condition on the ſurface, ſown with peaſe, in drills, in a cloſe manner, for the ſake of ſhade and the improvement of the land; which had theſe effects, beſides producing a good crop. The after-crops on it were likewiſe good.

As the ſoil above the ſlaty ſubſtance, in this part, was not above two feet and a half deep, the plan of ſetting off the ridges eight feet in breadth is ſaid to have anſwered well.

Drainage in hilly Lands and Sheep-Paſtures, with the means of procuring and raiſing Water for certain Purpoſes, &c.—In hilly diſtricts, and other ſteep places, where ſheep are the ſtaple or chief produce and ſtock of the land, leſs attention ſeems to have been paid to the drainage of ſuch parts of their walks and paſtures as are wet and unproductive, in the opinion of the writer of the work on draining, according to Mr. Elkington's principle, than to that of arable ground, although the effects in the one caſe are equally beneficial with thoſe in the other. This neglect is often attended with conſiderable loſs. From the nature of the herbage which a ſuperabundance of moiſture produces, whether ſtagnant on the ſurface, or long confined under it, proceeds that almoſt incurable malady the rot, to which ſo many thouſands of valuable animals fall a ſacrifice. For this, draining is a moſt infallible preventive; and in ſuch ſituations it is attended with little expence, as the drains may, for the moſt part, be left open, with here and there covered paſſages, over which the ſheep may croſs with ſafety. It is ſtated to be the practice, in many of the ſouthern ſheep-farms of Scotland, to cut ſmall open drains in the wet paſtures, only one foot in width, and the ſame depth; but this, it is believed, has very little effect either in carrying off the ſuperfluous water, or preventing the rot in the animals. One rood of ſuch a drain, as has been adviſed above, would anſwer theſe purpoſes, it is thought, more effectually than fifty of the other, and, on that account, would not be more expenſive.

And although in places where the depth of the cut does not reach the ſpring, the auger muſt be applied, no apprehenſion need, it is thought, be entertained of the holes filling up, where the drain is left open; for the force of the ſpring will, of itſelf, throw up any ſand or ſludge that may get into them, provided no great quantity of flood or ſurface-water is admitted. But the better to ſecure them againſt any obſtruction, ſmall openings may be made along the upper ſide of the trench: and in theſe the perforations may be made, leaving the mouth of the auger-holes about ſix inches or a foot higher than the bottom of the drain, which will be without the reach of the water that may accumulate in time of rains. From the irregular diſpoſition of the component ſtrata, the ſides of many hills are covered with alternate patches of wet and dry ſoil. By the appearance of the ſurface, and by the vegetables it produces along the declivity, the internal ſtrata, and manner in which they lie, may often be aſcertained with ſuch a degree of preciſion, as to guide the direction of a drain without inveſtigating *below* the ſurface; for the difficulty or facility with which ſuch ground may be drained, depends entirely upon the *lie* of the different ſtrata of which the hill is compoſed, and upon the perpendicular or horizontal inclination of the rock or body in which the water is contained. If the rock lies in a horizontal direction, all the different outlets or ſprings that appear on the ſurface may proceed from, or be connected with, the ſame body of water, and may all be *dried* up, by cutting off or letting out the main body of water that ſupplies them, at the lower part of the reſervoir, or place where the water would of itſelf run off more eaſily, if it was not confined under an impervious covering of clay. But, where the rock lies in a perpendicular manner, and contains only partial collections of water amongſt the more open fiſſures of the ſtone, which empty themſelves at numberleſs outlets unconnected with one another, it would be prepoſterous to attempt cutting them off by *one* drain, or by *tapping* any particular one of them, without a drain being cut into each. In this manner it is better to cut the main drain *all* in the clay, with ſmall cuts up to each outlet, than along the line or place where the ſprings break out, as it would in that direction be *too* much in the *rock*, and difficult to cut, from the nature and inclination of the ſtone. Where the water iſſuing out in certain parts, can, by means of the auger, be hit on in the main drain, at particular points it will be more effectually cut off; but if that is not practicable, the depth of the ſmall cuts will reduce it to ſuch a level as to prevent its overflowing or injuring the ſurface below. In many hills compoſed of alternate ſtrata of rock, ſand, and clay, the ſurface of the latter is commonly wet and ſwampy, while that of the former is dry and productive, and therefore requires as many cuts to drain it completely as there are diviſions of wet and dry ſoil. The higheſt part of the hill, being for the moſt part compoſed of porous ſoil, receives the rain-water which deſcends through it, till it meet ſome impervious ſtratum, as clay, which obſtructing its percolation any further downwards, it then riſes to the ſurface, and forces itſelf a paſſage over that impaſſable ſtratum. After it has thus overflowed the *upper* clay ſurface, it is immediately abſorbed by the next porous ſtratum, and, deſcending into it in like manner as above, it again iſſues at the lower ſide of it, and injures the ſurface of the next clay-bed, as it did that of the firſt. In this manner the ſame ſpring will affect the other ſimilar ſtrata of which the hill is compoſed, down the whole declivity, and form at laſt, in the hollow, a lake or bog, if there be not a proper outlet or deſcent to carry off the water. In order to drain a hill-ſide of this deſcription, it is neceſſary, it is ſaid, to begin by making a trench along the upper ſide of the *uppermoſt* ruſhy ſoil, which will have the effect of cutting off the higheſt ſpring; but as the rain falling on the next porous ſoil ſubſides to the loweſt part of it, and forms another ſpring, and as it may likewiſe be partly ſupplied from ſome other internal ſource, a ſecond cut is neceſſary there, to prevent that water from injuring the ſurface of the next clay-bed. Thus, ſimilar cuts will be requiſite lower down the deſcent, ſo far as the ſame ſprings and appearances continue to injure the ground, which may produce a quantity of water ſufficient to irrigate the lower ground, or which may be uſeful in ſome other reſpects and manners.

In ſome hills, the ſtrata of which they are formed lie ſo regular, that it is practicable to extract the water from either ſide on the ſame level, which would be a very conſiderable advantage in draining the one ſide, and in irrigating and procuring water for the other; for there is often found on the one ſide a wet ſwamp, and on the other the ſoil is too dry. This is owing to the bed of clay that upholds the water not lying horizontally, but *dipping* more to the one ſide than to the other, and by the one (the dry) ſide being *overlapt* by a covering of clay, whereby the water is forced to iſſue at the open ſide; but if an outlet is given to it on the *dry* ſide, by means of a drain lower than that from which it flows on the wet ſide, the courſe of the ſpring may be eaſily diverted. The oppoſite ſide being porous, and covered with ſand, will act as a reſervoir, to receive the rain-waters, which will afterwards flow through the opening made in the clay. This may be of great uſe in ſupplying a houſe with water that is ſituated on the dry ſide of the hill, and ſave the additional expence of conveying it in another manner. Care muſt, however, be taken in conducting the drain for conveying water to ſupply a houſe, &c. not to cut it or bore in it ſo deep as to reach a porous ſtratum, otherwiſe the water that may have been found at one place, may, by the ſame means, be loſt at another. Puddling may, it is ſuppoſed, in ſome degree, ſecure it, but not in every caſe.

A ſpring in a low ſituation, adjacent to higher ground, may be raiſed to ſupply a houſe, or for any other uſeful purpoſe, although much below that level, by confining it in a pipe, or brick chimney. The reſervoir from whence the ſpring or outlet of water is ſupplied being confined, and pent up between two impervious ſtrata, and the upper part of it extending perhaps to a conſiderable height and diſtance in the high ground, it is evident, that if a perforation be made through the ſuperincumbent ſtratum into the *tail* or loweſt part of the porous ſtratum containing the ſpring, the water may be raiſed by confining it nearly as high as the level of the head of the reſervoir. Of this kind there have been, it is ſaid, ſeveral inſtances in actual practice, where the water procured from draining low grounds has been raiſed to a conſiderable height above the level of the drains. The drains in ſuch caſes ſhould be cloſely built with brick, and puddled above with clay, to prevent the water from oozing through the joints. It is thus made to riſe, through ſome ſort of confined paſſage, to the height which is required, by the preſſure which it receives in the high ground. The advantages of ſuch operations, it is remarked, muſt be very great in many ſituations, and may often be accompliſhed with ſucceſs, where many would think them impracticable. Of the practicability of this, however, and that water may often be raiſed to a very conſiderable height, by means of its preſſure in diſtant ground, the following remarkable occurrence, which happened lately in digging a well in the vicinity of London, is a proof: earl Spencer, for the preſervation of his noble manſion-houſe at Wimbledon againſt fire, and to be well ſupplied with water, ordered a well to be dug at a little diſtance from the houſe, which was ſunk to the amazing depth of nearly 600 feet, before any ſpring was found. It was begun on the 31ſt of May, 1795; and on the 12th of Auguſt, 1796, the man who was employed in the undertaking, gave a ſignal to the perſon above to draw him up, as he had found the ſpring, and was immerſed in water ſo deep, that his life became endangered. In the ſpace of four hours the water roſe to the height of 350 feet, and during two days following its increaſe was more than a foot an hour. The water, proceeding from a rock, is remarkably fine, and, from the ſtrata it paſſes through, is ſtrongly impregnated with mineral qualities. As there is no extent of higher ground near that where the well is ſunk, and as the depth of it is ſome hundred feet below the bottom of the Thames, the ſource of the reſervoir from whence the ſpring is ſupplied, muſt be ſituated at a very great diſtance, and muſt contain a very large body of water to raiſe it ſo ſuddenly to ſuch a height.

There are many other caſes of wetneſſes in the deep moory or heathy grounds, which often take place and occupy the baſes of the narrow vallies at the bottoms of ſuch hilly lands, hang on the ſloping ſurfaces of their ſides, or ſpread over the more flat lands which lie at their feet.

The moſt ſimple caſe of this kind is probably that in which the more ſuperficial parts of the ſoil are of an impervious or porous nature, the ſubſoil of the abſorbent porous kind reſting upon a repellent impervious baſe or bottom; the porous ſubſoil part being uniformly charged with the deſcending waters, which are conveyed or brought down from ſome internal higher ſource, by a ſubſtratum of the gravel or other preconducting kind. In theſe circumſtances, where the under ſoil is ſufficiently free and open, a ſingle drain, properly made or cut acroſs the lower margin or edge of the riſing ground, may be fully equal to the prevention, even of the flatter lands below it, from being ſurcharged with water. But though this may be the caſe, ſuch an eaſy mode of removing the wetneſs may not always be the moſt ſuitable or proper, but muſt be decided upon by the full and mature conſideration of the particular caſe; as it is in caſes of this nature that waters for different uſeful purpoſes are to be procured, and the higher they may be drawn off, the more capable they will, for the moſt part, be of becoming beneficial in ſuch ways: beſides, where the abſorbent porous ſtratum of the lower lands is not ſufficiently open to permit the waters of a wet ſeaſon to paſs ſo freely through them as to prevent a temporary ſurcharge, a threefold benefit, it is thought by ſome, may poſſibly ariſe, by cutting and taking off the internal deſcending waters at the foot of the ſloping ground. As, in addition to the advantages already ſuggeſted, another good effect may be produced; which is that of taking off the *weight* of the waters which are pent up in the higher grounds from the lands below; and thereby relieving them from a common diſeaſe or complaint to which lands ſo ſituated are very liable; and which is occaſioned by the water, thus compreſſed, being forced up, through ſome fiſſure or defect in the ſoil, to the ſurface of the ground in ſome particular part or parts. But by a ſuitable fully efficient drain, made all along the upper margin of the flatter declining grounds, they may be entirely relieved from ſuch internal deſcending waters, and become in a healthy productive ſtate. It may, however, be added, that a drain ſo made, is in general more difficult and expenſive in cutting, than one which is formed at the lower part of the more flat declining land; the ſoil at the foot of a ſlope being commonly of a greater depth than it is either above or below that part; beſides the additional labour and trouble in cutting and ſinking the trench when to be ſoughed or filled, and ſtill more in keeping an open drain free, by reaſon of the greater preſs of water in that part. The upper ſide of the trench too, in ſuch caſes, is liable to ſhoot in; eſpecially if it be ſunk in a wet ſeaſon, the water acting the moſt forcibly there. Beſides, unleſs the trench be ſunk or cut down to a firm baſis or ſtratum, it is ineffectual; the lands below are ſtill liable to be affected with a portion, at leaſt, of the deſcending waters; beſides that which may fall on the particular ſurface of them. They conſequently demand nearly the ſame labour to render them dry, as they would without an ineffectual drain being made along their upper margin or border; notwithſtanding, however, in many inſtances, water, deſcending internally from a higher or more elevated ſource, and inſinuating itſelf beneath the ſuperficial ſoil of the lower grounds, ſo as to injure them, may be cut off by a drain running along at the foot of the hilly land, when cut or formed to a proper depth, as to the ſolid or impervious body; which may, at the ſame time, ſufficiently relieve the lands which are below, as well as afford a valuable ſupply of water for different economical purpoſes about the farm or ground.

Another caſe of this kind of draining is where the ſuperficial parts of the ſoil are of a porous or repellent quality, and the under or ſubſoil open or various, and partially charged with deſcending waters, paſſing through beds or veins of the ſandy, gravelly, or fiſſured rocky kinds. This is a ſituation of land which occurs more frequently than the above, but from which it principally differs, in the manner in which the internal waters act upon the lower lands. Inſtead of being diffuſed, in an uniform manner, beneath the ſoil, they enter or come into the ſubſtrata in collected ſtreams; and unleſs the ſubſoil be ſingularly open, and ſpreads out in an even manner, operate very irregularly on the land. Thus, if the ſoil be deep, and of an impervious or repellent quality, plots of cold wet land are formed and produced;—if thin, and of a porous freely abſorbent nature, moory excreſcences are raiſed on the ſurface; and if the ſtream be powerful and narrowly confined, a ſpring or fountain is the conſequence.

The nature of the means which are to be purſued in the removal of the wetneſs in this caſe is of a more complicated kind than in the preceding inſtance. In caſes where the ſupply of water cannot be cut off, the circumference of the flat ground is to be relieved by covered drains formed in a greatly declining manner from the diſeaſed parts, to a common drain or outlet in ſome proper place. In this caſe, the ſupply of water is cut off with leſs certainty, than when it is conducted by an evenly charged ſtratum, reſting on an impervious or repellent baſe or ſtratum. It may have only one, or many conduits ſituated at different depths. This too is a caſe in which the ſupply of water, with a ſufficient fall, may take place; and under circumſtances which particularly demand it, every expedient ſhould be had recourſe to in order to intercept the deſcending waters at the foot of the ſlope on the higher ſide of the lands which are to be drained.

A third caſe of draining in theſe ſituations is, where the ſurface-ſoil is impervious, or open and abſorbent; the under ſoil porous and abſorbent, with a cloſed bottom, and charged with deſcending waters, reſting on an impervious or repellent baſe, which has an under baſe that is open and freely abſorbent. This is a ſituation of land that may not often occur in ſuch a ſtate as to have the ſtratum or baſe on which the water reſts, only of a few feet in depth or thickneſs; but in which, it is probable, an open or porous ſtratum may not unfrequently be found, by careful examination, at a greater depth; particularly when the land is ſituated below riſing ground, at the baſe of which ſuch a ſtratum is indicated to be preſent, by the flowing of a natural ſpring or fountain.

The means of removing the wetneſs in ſuch a caſe as this, is obviouſly that of opening a communication between the impervious or cloſed and the open porous ſtrata; in order that the injurious waters, which are pent up in the former, may be permitted to paſs down into the latter. It is in this way, it is ſaid, that marle-pits are drained in ſome diſtricts, as in Norfolk; the beds of marle which hold up the water being cut through ſo as to let it down into the great body of ſand on which they reſt. In order to effect which, a large earth borer naturally preſents itſelf; and where the ſubſoil is *free* and open, and the ſurface-ſoil in a ſtate of *perennial herbage*, the operation of it, when duly directed, and performed in a ſuitably dry ſeaſon, may be found very effective for the time, if not durable: in the practical management of which a thick turf is to be raiſed on the ſurface, and at the bottom of the little pit which is made thereby, the borer is to be inſerted, the turf being returned into its place, as ſoon as the work has been completed, in order to prevent extraneous matters from getting into and obſtructing the opening made by the borer.

In land under the *arable* ſtate, the operation may not, it is ſuppoſed, be ſo efficient; but, however, if pits were ſunk down beneath the ſoil, it is ſuggeſted, ſo as to ſecure the tops of the bores from the operations of tillage, as to the depth of twelve or fourteen inches below the ſurface, ſods being then laid over the tops of the bores, and the excavated ſoil or mould returned to their places, ſuch drains might continue efficient for a ſhort length of time. In caſes, however, where the ſubſoil is ſo *tenacious* as to ſtand in need of many drains to draw the water effectually out of it, this mode of draining, or the uſe of the borer, it is thought, would appear a leſs eligible practice. In the bottom of a drain, whether open or covered, more or leſs current takes place, by which earthy matters are liable to be waſhed down into the bores; and theſe, in conſequence, to be choaked up. The operation and effects of water falling down a pipe or tube, and that of its riſing in them, are, it is thought, perfectly different; as riſing waters looſen, and force upwards the obſtructing matters they may meet with in their paſſage; whereas falling water, on the contrary, adds the preſſure of its own weight to that of the obſtructions; and by diſſolving earthy matter, and thereby filling every chink and cranny, tends to cloſe up the paſſage in the moſt effectual manner. Riſing waters too enter the pipe or tube in a pure ſtate, leaving their impurities below, while falling water carries down with it all the foulneſs that its current is capable of bearing to the mouths of the orifices of ſuch pipes or tubes. Hence, even under the firſt mentioned circumſtances, it is probable, it is ſaid, that the ſalutary effects of the bores would only be of a temporary nature. Beſides, where drains are neceſſary to extract the water from the ſubſoil, why, it is aſked, may it not be collected into a body, and be carried away upon the ſurface, where it may in many caſes be applied to different uſeful purpoſes?

Where, however, a ſuperficial deſcent cannot be had for the water thus collected, and an open ſtratum lies beneath the ſubſoil, which is ready and fit to receive it, the making of a communication between them becomes a point of great advantage and importance; as the trouble and expence of raiſing and removing the water by other means may be avoided.

In all ſuch circumſtances of land in theſe ſituations, the loweſt point of the ſpace of ground to be drained is to be aſcertained, in which it is adviſed to ſink a ſhaft down into the receiving open ſtratum, which is then to be filled up, to within a few feet of the ſurface, with rough clean ſtones, the roots of trees, or other open materials; on the top of which a filter is to be formed with heath and gravel, or any other ſubſtances which will prevent earthy matter, or water in a foul ſtate, from entering the ſhaft or opening. The collected waters are to be led to this filtering drain or opening in all caſes.

Where, however, the water is collected by means of covered drains, and where the filtering parts have likewiſe coverings placed over them, the whole proceſs will, it is ſaid, be free from external injury; and drains or works of this kind might, it is ſuppoſed, remain unimpaired for ages, or a very great length of time. Even if the waters were collected by open drains, and the filters, or filtering parts of them, were ſuffered to continue in a ſtate of neglect, until the ſhaft, in the courſe of time, ſhould become defective, the remedy, it is thought, would be eaſy; as by embracing a dry ſeaſon to re-open it in, and to clean it, as well as the materials with which it may have been filled, from their impurities, it may be reſtored to its original condition at but little expence or trouble. It may be noticed further, that where the land to be drained and improved is liable to have any other ſurface-water coming upon it than what falls upon its own ſpace, ſuch waters ought to be drawn and conducted away from it ſuperficially, by cutting it off at ſuch a height as will gain a ſufficient fall. And further, when the quantity of water which deſcends into it ſubterraneouſly, or which would deſcend into it if a free paſſage were opened for it, is found to be too copious to be readily diſcharged by ſuch a drain or ſhaft in the manner here propoſed, proper means ſhould be taken to cut off the ſupply, or as much of it as may be, by making a perforated trench, or otherwiſe, at a ſufficient height to be able to convey it away in a ſuperficial manner; and with a ſuitable fall, ſo as to prevent its entering the ſpace of land to be improved; which by this means will only have its own ſuperfluous waters to diſcharge by the ſhaft-drain. See Shaft-*Drain*.

There are many inſtances of low, flat-lying, moory vallies in different diſtricts of the kingdom, and eſpecially in Norfolk, from the baſes of which it would be difficult to make ſuperficial drains, which have for their ſubſtrata or ſubſtructures, moſt probably, inſatiable beds or depths of ſand, or ſandy matters, in which this mode of draining might, it is ſaid, be practiſed with vaſt benefit. The practice in theſe caſes alſo affords additional explanation of what has been ſaid above, in ſpeaking of the removal of the wetneſs of land by perforating through a retentive ſtratum to the porous one below, as well as the nature of the drainage in bogs ariſing from ſprings.

In caſes where the ſuperficial ſoil is impervious and repellent, or porous and abſorbent, the ſubſoil being uniformly abſorbent, but cloſed in the bottom part, and charged with riſing waters, the effect produced varies in ſome meaſure with the nature of the ſurcharged lands. Where the abſorbent ſubſtrata are imperfectly cloſed, or where the ſurcharging waters find ſome other partial vent at the ſame level, the effect is merely that of an under ſoil, which is liable to be ſaturated in a wet ſeaſon, and which is left dry after a long continued drought. But where the ſubſoil of the land to be improved, together with the ſubſtrata in its vicinity, on the ſame level, are equally impermeable, and the *embanked* waters are, in conſequence, under the neceſſity of riſing, for a vent, to a higher level, the lower lands become ſubjected to perpetual ſurcharge: even the ſurface-ſoil, when in any degree abſorbent, becomes liable to a ſimilar degree of ſaturation, by reaſon of the weight of water which lies above it; as the compreſſed waters, acting in conformity to the general law of fluids to gain a common level, preſs upwards againſt the ſoil: and where this is freely and uniformly abſorbent, it becomes fully ſaturated; the inevitable effect of which is a bed of ſuper-aquatic plants; and, in the courſe of time, an extent of deep moory bog: if partially abſorbent only, plots of moor are the conſequence.

The means of relief in caſes of this nature are much the ſame as thoſe in the firſt of the above caſes. Where the ſubſoil is uniformly free, and a ſupply of water is not wanted above what is called the running level of the lower margin of the land to be improved, a trench, with a ſufficient outfall there, will lay the whole effectually dry; and will, in addition, become the common outlet of the internal waters; inſtead of the natural ſpring, which will conſequently ceaſe to flow.

But if, on the contrary, the ſubſoil be not ſufficiently open to permit a free paſſage for water through it, or where economical intentions demand a fall from the upper margin, it will be right and proper to attempt to take off the head and weight of the water, by a trench made at the foot of the hill; and then to free the ſpace of land diſeaſed by one or more drains, as the particular circumſtances of the caſe may direct. Where a ſupply of water is particularly deſirable, or the improvement of cold lands, hanging on the ſlopes of riſing grounds, is wanted, it may be the moſt proper, when it is found that a deep trench alone, made at the foot of ſuch ſlopes, by reaſon of the too great depth of the impervious or repellent materials, is inſufficient for the purpoſe, to try the effect of the borer, and by this means endeavour not only to accompliſh the ſupply of water that may be deſired, but by bringing down the ſurface of the ſubterraneous collection to a level with the bottom of the trench, to relieve the plain below from the upward preſſure; and thereby probably remove the evil in a ſufficient manner, eſpecially on the higher ſide, without additional trouble and expence.

In caſes ſimilar to the above alſo, where a freely conducting ſtratum, which is charged with water, lies too deep to be eaſily reached by a trench, and too level to be relieved by the borer, and in all caſes where the water lies too low, and in too flat a ſituation to admit of a ſuperficial channel being ſunk deep enough to draw it from its natural bed, yet without an open ſtratum beneath to render a ſhaft-drain effective, a well-drain ſunk in the loweſt part of the ground to be improved, may, it is ſuppoſed, be had recourſe to with good effect. See Well-*Drain*.

In caſes where the quantity of water to be raiſed is conſiderable, and the depth at which it lies not more than ſix or eight feet, it may be forced up into an open drain, ſunk to about half the depth, by the uſe of the common draining-mill of marſh-land diſtricts: or, where the depth is too great, or the ſuperſtrata too looſe and unſtable to admit of a deep open drain, and that of an arched one too expenſive, a pump wrought by wind, or by water, where a ſufficient ſtream can be commanded, may be ſufficient to raiſe it to the ſurface; care being taken in this, as well as the above caſe, that no extraneous waters interfere. See Surface-*Draining*.

There are other caſes of draining beſides theſe, in which the wetneſs is removed by drawing off the ſprings that cauſe them. See Tapping *Springs*.

Caſes of the ſame nature as thoſe given above are illuſtrated by means of ſections, in all the different inſtances, by the writer of the work on "Landed Property."

In many caſes too, a great deal is capable of being effected in theſe and other ſorts of hilly grounds, and very aſtoniſhing effects produced, in ſome inſtances, by means of cuts or drains alone, properly directed, without the neceſſity of either boring, or having recourſe to the making or ſinking of pits in the land, for removing and taking away the wetneſs. It has been found that fields or grounds of conſiderable extent, which lie upon irregular banks, hills, or knolls, have been readily drained in this manner; though the water which roſe and iſſued out from the ſprings in particular parts of them, rendered them before of but very little value: and though many drains, in improper directions, and not properly cut, had been before formed in them, at great expence, for draining off the wetneſs without effect. This has been accompliſhed by cutting drains to ſuitable depths through the porous ſubſtrata, and in ſuch directions as to cut off the ſprings coming from the higher grounds; or to take the water of them away, which lodged in the hollow parts of the land. Such drains have often ſpeedily removed the wetneſs, without coſting a tenth part of what was paid for the others, or taking into the account the difference of keeping them in order, which muſt be a mere trifle, when compared with that of the others, as they were moſtly on a looſe bottom, and made ſo ſmall, as to be readily choaked up and deſtroyed. The nature of the ſituation, and the lie of the ſtrata of which ſuch lands are formed and compoſed, readily explain the reaſon why the moiſture in ſuch caſes is ſo quickly removed by properly cut and directed drains, as it ariſes, in moſt inſtances, from the inclination of the ſtrata, which is commonly towards the hollow parts of the grounds, and from their frequently terminating on the ſides of ſuch banks, hills, or knolls, under the impervious, clayey, marly, or ſtiff loamy ſtrata, though for the moſt part upon them.

Miſtakes in the modes of cutting the drains, and in the directions they ſhould have for properly intercepting and taking away the water of the ſprings, are almoſt every where in ſuch caſes committed, and vaſt expence thereby not unfrequently incurred; it is conſequently of much importance, in all ſuch inſtances, to have a proper plan laid down before any part of ſuch works be undertaken.

There are ſometimes ſprings and wetneſſes found on the tops of banks and hills, where the ground which is contiguous is much lower on all ſides; but in ſuch caſes they are, in many inſtances, ſupplied with the water from higher ground at a diſtance, by means of metallic, mineral, or other ſubſtrata, lying in a particular curving direction, between impervious ſtrata, from the higher parts of the land to the lower. The ſprings, in theſe caſes, iſſue forth at the points where the metals *crop* out.

The drainage, in ſuch caſes, is to be accompliſhed by forming ſuitable outlets for the water, and by boring or ſinking pits through the porous or metallic ſtrata, ſo that the water flowing through them may be intercepted, and reduced to ſuch a level, that the ſource of the ſprings may be cut off, and the ground on the top and on both ſides of the declivity become dry. By this means the metals, to that depth, may be rendered capable of being wrought, without any inconvenience from the water.

In the above method, the continuation of the ſtrata is ſuppoſed to keep on the ſame riſe, in the high ground on the north ſide of the rivulet, to a much higher level than the line of ſprings, by which means, the ſprings iſſuing from the *crop* of the metals are ſupplied.

By bringing up a cut from the rivulet into the bank an outlet will be obtained for the water, free from that of the rivulet; and by boring or ſinking a pit, the water flowing through the porous ſtrata will be reduced to a level, and of courſe the ſource of the ſprings will be intercepted, and the ground on the top, and on both ſides of the declivity, become dry; and the metals, to that depth, may be wrought free of water.

This could not be effected by boring from the bottom of the rivulet, or any run of water, for the preſſure of the running water above would prevent that below from riſing freely, and ſmall ſtones or ſand would be lodged in the hole. If the ſtrata crop out to the ſurface, and cauſe wetneſs, the pit or bore may be continued till it reach it; but lying at ſuch a depth, and covered with ſo much clay on the ſurface, the water contained in it may do no injury to the ground above it.

Drainage in Lands compoſed of alternate Beds of Clay and Sand; and other mixed Soils.—In diſtricts where the ſoil is compoſed of an intermixed variety, and where clay forms the moſt predominant part, draining is, according to the firſt writer above noticed, a work attended with much greater difficulty and expence, than in thoſe where both the ſurface and internal ſtrata are more regularly diſpoſed. In theſe kinds of ſoils, where every reſervoir of water is unconnected with another, being ſeparated by intervening beds of clay, the partial collections of water that theſe reſervoirs contain are ſo much augmented in time of great rains, that, being full to the level of the ſurface of the ſurrounding clay, the water having then a free iſſue, as over the edges of a diſh, ſo overflows and ſurcharges the ſurface of that clay, and renders it ſo wet and ſour, that its produce becomes every year more ſcanty, and the nature of the ſoil itſelf more barren. As theſe ſand-beds have no communication with each other, it requires as many drains as they are in number to extract the water from each of them. From the neareſt and loweſt part of the field to be drained, a trench muſt be cut up to the higheſt or moſt diſtant ſand-bank, in ſuch a direction, as, if poſſible, to hit on ſome of the intermediate ſand-beds, and ſave the making a longer ſide-cut, otherwiſe neceſſary; but where this would give many aukward turnings to the main trench, it would neceſſarily lengthen it; and where, by croſſing the beds in places higher than the ſurface of the ſurrounding clay, it would conſiderably increaſe the depth of it, and be difficult to work, eſpecially if rock or running-ſand; drains in form of the letter Y muſt branch off to ſuch beds, to draw off the water they contain, and convey it into the leading one. Although the ſand-beds throw out the water they contain on all ſides, ſo as to injure the clay-ſurface immediately round them, a drain on the one ſide will completely extract the water from the whole, and prevent it from breaking out at either ſide, provided that where it is cut be the loweſt. It may be obſerved, that unleſs the drain is ſo cut, it cannot be ſuppoſed to have this effect, while the water can find an outlet on the oppoſite ſide of the bank, lower than the bottom of the drain. This ought, therefore, to be previouſly conſidered; and by carefully examining the ground, and applying the ſpirit-level, the proper ſide for the drain may eaſily be found: or, if the water burſting out round the bank has been obſerved in dry ſeaſons to run at one place, and not at others, it is a proof that this is the loweſt point; and by cutting the drain in the direction of this level, the water will afterwards be prevented from riſing to the height of the upper outlets, or above the level of the bottom of the drain, even in the wetteſt ſeaſons. In many caſes, the whole water that cauſes the wetneſs, and ſupplies the other ſand-beds below, may ariſe from the upper ſprings, paſſing over the upper ſoil, and through the different ſand-beds; by being prevented from deſcending deeper than the retaining bed of clay. In this caſe, the drainage of the whole field may be accompliſhed with much leſs difficulty and expence than in the former. After the main conducting drain from the outlet has been cut, a drain on the upper or higher top part, quite acroſs, muſt next be made, which will intercept and cut off the principal ſprings, and may by this means render the lower drains, on the different ſides of the main conducting one, unneceſſary, unleſs merely to extract the partial ſupply of water which the lower ſand-beds may receive in time of rains, and which, where theſe ſand-beds are of ſmall extent, can do little injury to the adjoining ſurface. From this it appears, that one ſpring riſing in the higheſt ground may be the ſole cauſe of injuring a conſiderable tract lying below; from its water overflowing the ſurface at one place, and ſubſiding into it at another, according to the tenacity or openneſs of the ſoil; and therefore, in ſuch caſes, the upper ſpring, or *feeder*, ſhould be firſt cut off, and the effect of that known, before any more drains are made in the lower ground.

Beſides ſoils correſponding to this deſcription, there are others nearly of a ſimilar nature; but each bed being of leſs extent, and lying more regularly together, their drainage can be more eaſily effected, by means of leſs cutting, and conſequently leſs expence. Under the beds of ſand and clay that thus lie alternately together, and almoſt parallel to one another, is found a general body of impervious clay, that keeps up the water contained in the ſand, which continues always full, moiſtening the adjacent clay, and, in wet ſeaſons, running over it. As this *main under-ſtratum* of clay is ſeldom above four or five feet below the ſurface, a drain muſt be cut to that depth through the middle of the field, if it have a deſcent from both ſides; or, if the ground declines all to one ſide, the drain muſt be cut there, where the water will more eaſily diſcharge itſelf into it; and, unleſs the field is of a conſiderable extent, and have more hollows in it than one, one drain will anſwer the purpoſe effectually; for, by croſſing all the different beds that hold the water, it will draw it from each.

The great difficulty, however, in draining lands of this deſcription, and which is impracticable by one drain, is, if the direction of the alternate beds of clay and ſand lie *acroſs* the declivity of the grounds; ſo that one drain, in this caſe, can have no other effect than that of carrying off the water after it has paſſed over the different ſtrata, and would here naturally ſtagnate in the loweſt part of the field, if there was no other outlet for it: therefore, when the ground lies in this manner, which is often the caſe, beſides the drain in the hollow, others muſt be cut up from it, in a ſloping direction, *acroſs* the declivity, which by croſſing all the different veins, or the very thin and narrow ſtrata of ſand, will extract the water from each. Where theſe alternate ſtrata are of great extent, and the wetneſs produced by greater ſprings forming ſwamps at different levels on the ſide of the hills, the method of draining them has been already deſcribed.

The firſt thing to be obſerved, in the drainage of ſuch alternate ſoils, is to diſcover minutely the inclination of the alternate ſtrata, or how they lie with regard to the ſituation of the field to be drained, as upon this the direction of the drain entirely depends; and as the external ſigns that diſtinguiſh the different beds are eaſily perceptible, from the appearance of the ſurface, and difference of the herbage that each produces, there is little difficulty in attaining this part of the object. In drains of this kind there is ſeldom any need for applying the auger, as the neceſſary depth of the trench reaches far enough down; and as there is no ſpring for want of connection with the higher ground to force itſelf up through the auger-holes, or, if there is, it cannot, at ſo great a depth, and below ſuch a body of clay, do any injury to the ground above.

The drain, after being formed like a ſough at the bottom, or ſet like a triangle, muſt be filled a conſiderable way up with ſmall ſtones, before the mould is thrown in, taking care to have *tough* ſods laid immediately above the former. Where ſtones are ſcarce, and plenty of bruſh-wood at hand, faggots may be ſubſtituted in their place with propriety. The under part of the drain, however, ſhould be laid or *coupled* with ſtones, as a canal to carry off the water ſubſiding through the faggots; and which has alſo the good effect of prolonging their duration; for when the water cannot get off, which muſt be the caſe where there is no open conduit of ſtones, its ſtagnation amongſt the branches muſt ſoon cauſe their decay, and choak up the paſſage of the drain. In no caſe whatever ſhould the drain be filled with ſtones thrown in in a promiſcuous manner, without a courſe for the water at the bottom being firſt formed. There is one thing more to be attended to in completely accompliſhing the drainage of theſe ſoils: if the field lies very much on the deſcent, care muſt be taken in laying out the *branch*-drains in a direction ſufficiently horizontal, ſo as not to make the fall too precipitant, by which the bottom of the trenches would be worn uneven, and this would obſtruct the paſſage of the water, which might ſoon blow them up; but the fall ſhould be ſuch as to enable the water to clear its courſe. The reaſon why fewer drains are required in fields that lie nearly horizontal, as thoſe of the ſecond kind here mentioned, is, that the water is drawn equally from both ſides, whereas thoſe on a ſloping declivity, drawing only from the higher ſides of the drains, require them to be more in number, or cloſer to one another. This is the caſe in every ſituation where ſurface-draining is neceſſary, and particularly ſo in ſome ſorts of ſoils, as will be ſeen deſcribed in that kind of draining. See Surface-*Draining*.

In Lancaſhire, where theſe ſoils, compoſed of alternate beds of clay and ſand, very much predominate, and which have there acquired the names of *ſand-pots*, or *guts*, a term properly enough applied to them from their holding water like a pot, it is obſerved, that ſeveral drainages have been executed by Mr. Elkington in the manner here deſcribed, and alſo a very difficult one of the ſame kind at Sutton-Hall, Derbyſhire, where the water was contained in ſmall beds of rock, croſſed and intercepted by beds of clay.

There are ſtill other caſes of theſe intermixed ſoils, ſuch as thoſe which have a porous, or partly impervious ſuperficial ſoil, while the under-ſtrata are conſtituted of different diſtinct maſſes of impervious repellent materials, diſpoſed in a regular manner. The lands which lie near the bottoms of hills and ſlopes are often compoſed of ſuch impervious maſſes of the clayey, ſtrong marly, or ſtiff loamy kinds. Such an intermixed, irregular conſtruction of land, has naturally the effect of forcing the internal waters, which deſcend from ſprings in the higher grounds, as well as that which is taken up by the ſurface-ſoil, where it is porous, upwards towards the ſurface of the lands, or other directions, ſo as to cauſe or induce wetneſſes which have different appearances, according to the nature or quality of the ſuperficial parts of ſuch grounds, as wet, ruſhy, ſedgy, or other cold moiſt lands, oozing, ſpringy, wet lands, land-ſprings, quagmires, quickſands, and actual ſprings of water, either of the temporary or more permanent kinds, as the circumſtances of the ſeveral caſes may be.

The means of draining ſuch intermixed portions of wet ground of this ſpringy nature, although attended with ſome difficulty, is moſtly capable of being accompliſhed without any very great trouble or expence; this is to be effected by cutting up from the main conducting drain, which ſhould always be carried through the moſt depending maſſes, ſmall drains into the ſeparate upholding maſſes or ſtrata, at ſuitable depths, ſo as to find the waters which reſt upon them and draw them off. Such drains, where properly made and directed, muſt not only be effectual, but durable in their nature. The bottoms of the drains or channels in all theſe caſes ſhould conſtantly be cut a few inches into the firm impervious beds or ſtrata, and their higher ſides be made to communicate well with the openings in which the waters are lodged. In theſe ways this ſort of land may, in moſt inſtances, be rendered perfectly dry, and in a ſtate fit for cultivation.

A full and perfect knowledge of the buſineſs of ſpring-draining is of the utmoſt utility and importance; as more labour and money have, probably, been uſeleſsly thrown away upon this ſort of rural improvement than that of any other, merely for want of ſuch information. In many caſes, from three to five times as much money may have been expended, and trouble cauſed, as the nature and circumſtances of the different caſes demanded. It is indeed not improbable, but that for one-fifth part of each, the buſineſs might, in different inſtances, have been more effectually and completely performed, if the perſon employed had been ſufficiently informed on the ſubject. It has been the too common practice of the ordinary claſs of drainers, in removing the wetneſs cauſed by ſprings, whether from intereſt and deſign, or the want of adequate knowledge, to fill the ground with a number of drains, cut ſo as to ſpread and extend themſelves in all directions, wherever the ſlighteſt appearances of moiſture or wetneſs preſented themſelves; while in all probability, by the cutting of a ſingle drain in a ſuitable and proper direction, ſo as to intercept the ſprings, or draw off the internally collected waters, which cauſed ſuch wetneſſes by their ſpreading branches, the whole of the land might at once have been effectually laid dry. The prevention of this uſeleſs waſte of labour and money is only, perhaps, to be found in the endeavour to bring the nature of the theory and practice of this ſort of draining into a more clear and comprehenſive point of view, ſomewhat in the manner which has been attempted above, ſo as to enable thoſe who undertake this kind of buſineſs, to ſuperintend and direct all the various operations and proceſſes of it in the moſt ſuitable, proper, and efficient manner, without incurring unneceſſary expence. There can be no doubt that improvements of this principal kind in land would be much more generally attended to and extended than they are at preſent, if this were the caſe, and the ineffectual modes in which they are executed, in too many different inſtances, leſs frequent. As the chief and beſt ſkill of the artiſt, in this ſort of buſineſs, probably lies in the readineſs and certainty with which he is capable of diſcovering the main ſprings, collections, and paſſages or channels of the water which produce the different kinds of wetneſſes which are to be removed; and as neither long cuſtom, nor the moſt extenſive practice, has hitherto been ſufficient to lead to the means of attaining theſe, in all caſes, even when guided and aſſiſted by the outward ſuperficial appearances which the ſurface of the ground may afford; it is ſomewhat extraordinary that other aids and methods have not been had recourſe to for the purpoſe. This has, however, ſo far as we know, not been at all attempted until lately, and yet in one or two inſtances only. The ingenious drainer of Trafford-moſs, in Lancaſhire, as already noticed, has contrived a pump for this uſe, which is to be put down into the ſoil in different places, in order to aſcertain the preſence of ſprings, or collections of water in it, before the work of draining is begun. It is an implement of very ſimple conſtruction, and ready application, and which may be of very great utility in this intention. See Spring-*Draining Pump*.

The writer of the work on "Landed Property" has alſo ſuggeſted, that the borer is a tool which particularly preſents itſelf as uſeful in this way. On the ſuppoſed ſimilarity of the modes of ſearching for ſprings or internal waters, and for mineral or foſſile ſubſtances, it is thought extraordinary that the ſame method of proceeding ſhould not have long ſince been adopted. In the latter caſes, in freſh diſtricts, the work of ſearching for coal is not, it is ſaid, begun by ſinking a ſhaft, though appearances may be ever ſo favourable; the ground is firſt tried by the borer, at a comparatively trifling expence, to aſcertain the proper place of ſinking the pit. In trying for other matters, as ochres and other ſimilar kinds, the ſame tool too may be ſaid to be that which is in common uſe. And there can, it is thought, be no riſk in ſaying, that it may be equally well and more profitably employed, as a common tool of the drainer, for the purpoſe of *finding* the ſprings, reſervoirs, and channels of ſubterraneous waters, in the practice of that art, and by which it may be reſcued from the difficulty and myſtery in which it has hitherto been ſo greatly involved. See Borer.

It is ſtated, that an inſtance in the practice of a firſt-rate drainer has been ſeen, in which the uſe of the borer, for the purpoſe of *finding* the water before the ſpade was ſet to work, would have ſaved a large ſum of money, which had been laid out under an error in the mode of practice which had been purſued.

There will be ſome difference in the depth and manner of uſing the tool, according to the circumſtances and diſpoſition of the land, and the intentions and methods of the draining which are to be undertaken, as has been ſhewn already in conſidering the nature of the drainage in different caſes. And it may be neceſſary and convenient to have the bores and boring rods properly marked and regulated, eſpecially in particular caſes.

Thus, though there may be ſome inſtances of wetneſs in lands, in which it may be eaſy at once to judge and determine, with a great degree of certainty, of the nature and ſituation of the cauſes by which they are produced, and conſequently to operate and perform the means of their removal without any difficulty or trouble of this ſort; there are ſtill numerous others, in which the uſe of ſuch tools and implements may be of the higheſt and moſt material importance and advantage, not only in pointing out, with accuracy, the peculiarity of their ſituations and directions, but in preventing uncertain and unneceſſary cutting, and thereby procuring conſiderable ſavings in different ways. They muſt, of courſe, contribute much to render the practice of ſpring-draining more complete and perfect.

Spring-*Draining Auger*, that ſort of tool which is employed in this kind of draining for boring down into the ſubſtrata of the earth, after the drains have been dug, and tapping or letting off the ſprings, or for perforating the ſtiff ſoil or other parts, and letting the water down into a porous ſtratum below. It is a tool of very great utility in this ſort of draining, and which has much ſimilarity to that which is employed in ſearching for coal and other ſubterraneous minerals. The auger, or ſhell part that forms the hole or bore in the earth or ſtrata through which it paſſes, is moſtly from about two and a half to three inches in diameter; the hollow portion of it being about one foot four inches in length, and conſtructed nearly in the form of the common auger of the carpenter, only the ſides of the ſhell part are made to come cloſer to each other. The rod parts are formed in ſeparate pieces, of four feet long each, which ſcrew into one another, to any ſuitable length, one after another, as the depth of the hole or bore may require. The ſize of the ſtem above the auger part is about an inch ſquare, except at the joints, where, for the ſake of ſtrength, they are a quarter of an inch more. There are alſo a chiſſel and punch for ſcrewing on, in going through hard gravel, or metallic ſubſtances, in order to expedite the paſſage of the auger, which could not otherwiſe perforate ſuch hard bodies. The punch is often uſed, when the auger is not applied, to prick or open the ſand or gravel, and give a more eaſy iſſue or diſcharge to the water. The chiſſel is an inch and a half or two inches broad at the point, and made very ſharp for cutting ſtone, and the punch an inch ſquare, like the other part of the rods, with the point ſharpened alſo. There is a ſhifting handle of wood, which is faſtened with two iron wedges affixed to it, for the purpoſe of turning round the rods in boring, and alſo two iron keys for ſcrewing and unſcrewing the rods, and for aſſiſting the handle when the ſoil is very ſtiff, more than two men being required to turn the tool.

It is remarked by Mr. Elkington, that it has been conſidered a difficult part of the buſineſs of draining, to judge properly when to make uſe of this boring tool. Some, it is ſaid, who have not ſeen it employed in this ſort of work, have been led into a miſtaken notion, both as to the manner of uſing it, and the purpoſes for which it is applied. They think, that if, by boring indiſcriminately through the ground to be drained, water be found near enough the ſurface to be reached by the depth of the drain, the proper direction for it is along thoſe holes where water has been found; and thus make it the firſt implement that is uſed. The contrary is the caſe, the auger being never made uſe of until after the drain is cut, and then for the purpoſe of perforating any retentive or impervious ſtratum lying between the bottom of the drain and the reſervoir or ſtrata containing the ſpring. Thus it is capable of greatly leſſening the trouble and expence that would otherwiſe be requiſite in cutting the trench to that depth, to which, in many inſtances, the level of the outlet will not admit. See SPRING-*Draining*.

The manner of uſing the tool in working of it is ſimply thus: two or rather three men are neceſſary. Two ſtand above on each ſide of the drain, who turn it round by means of the wooden handle; and when the auger part is full they draw it up out of the hole, and the man in the bottom of the trench clears out the earth with the inſtrument for the purpoſe, aſſiſts in pulling the auger up out of the hole, and in directing it into it again, and can alſo aſſiſt in turning with the iron handle or key, when the depth and length of the rods require additional force to perform the operation. The workman ſhould be careful in boring, not to go deeper at a time, without drawing, than the exact length of the ſhell, otherwiſe the earth, clay, or ſand, through which it is boring, after the ſhell is full, may make it very difficult to pull out. For this purpoſe the exact length of the ſhell ſhould be regularly marked out on the rods, from the bottom upwards. Two or four flat boards, with a hole cut into the ſide of one of them, and laid alongſide of one another over the drain, in the time of boring, are of very great uſe for directing the rods in going down perpendicularly, for keeping them ſteady in boring, and for the men ſtanding upon, when performing the operations.

The *horizontal* draining auger is another tool of this kind, which was invented in Leiceſterſhire, and is probably not yet become well known, or in general uſe. It is capable, however, of having conſiderable utility and application in the practice of ſpring-draining, as well as in other ways. It has the advantages, in many caſes, of greatly leſſening the expence of cutting, that would otherwiſe be neceſſary, and of performing the work in a much ſhorter ſpace of time. It may be of great benefit when employed for forming a ſuitable paſſage for the water without opening a trench-drain, where the water of a drain, brook, or rivulet has to paſs under a bank, hedge, road, wall, or any other ſimilar place, and where pits are to be laid dry; as well as in many other caſes, as for tapping ſprings, or detecting water at the bottom parts of hilly lands, in order to the draining of the ground or the ſupplying of the water for different uſeful purpoſes, as the water of the ſprings, in theſe caſes, when it may be hit upon, will flow with more facility and readineſs, as well as in greater abundance, through ſuch horizontal or level openings, than through perpendicular outlets. It may likewiſe be uſeful for laying or putting down leaden pipes for the paſſage or conveyance of water, in making the holes into which the pipes may be introduced, and laid without the neceſſity of forming open cuts for the purpoſe, which are often very laborious and troubleſome in performing.

The manner of uſing the tool in working is this: where, for inſtance, water is to be diſcharged from any ſituation in which it is contained, that has high banks ſurrounding it, if the land declines lower on one ſide, after finding the level of the bottom of the water on that ſide, it is to be traced to the face of the bank, where the perforation is to be made through it by the auger. In doing which, the ſurface of the ground is there firſt to be made ſmooth, ſo as to place the frame of the tool nearly level, with the auger part of it pointing a little upwards. It is then to be wrought, which is done by two men turning the handles at the top part. When the auger or ſhell part is full, the rods are drawn back by reverſing the lower handle, and other rods may be added at the joints when the diſtance requires it. In boring or working through a bank compoſed of the hardeſt clay, or other ſuch materials, two men will, for the moſt part, get through from thirty to forty feet in the courſe of a day, if they be not obſtructed by hard ſtones, or other ſuch matters, which will require a chiſſel to be fixed on in the tool in the place of the ſhell, and longer time in working through. Where the length or diſtance to be bored or wrought through is conſiderable, and longer than the whole length of the different rods when ſcrewed together, a pit or opening is neceſſary to be dug or ſunk down, at a ſuitable diſtance, upon the line to the proper depth of the hole, for placing the frame and tool in when removed from its former place, and the work be then carried on in the ſame manner as before in the former part of the operation.

SPRING-*Draining Level*, that ſort of level which is employed in forming and cutting drains where ſprings are concerned. It is the ſpirit-level which is, for the moſt part, made uſe of in caſes of this ſort, and which ſerves to aſcertain, after a principal ſpring has been diſcovered, a line on the ſame level, to only one, or the different ſides of it, in order that the direction of the drain may be better and more certain. The uſe of it is moſtly the firſt and moſt important work in ſetting out drains in this ſort of drainage. It is employed in determining the level from one particular ſight, or from different ſtations, for a conſiderable length or diſtance. It is alſo neceſſary to decide the quantity of fall that can be gained from a drain to the neareſt outfall or outlet for the diſcharge of the water, as the more ſhort that is the better, when ſufficient fall can be had. It has likewiſe ſeveral other applications in the practice of ſpring-draining, as may be ſeen in ſpeaking of implements or contrivances of this nature. See LEVEL.

Scarcely any thing can be done, in this or any other mode of draining, nor even in irrigating or watering land, without the uſe of a proper level of ſome kind or other.

SPRING-*Draining Pump*, that ſort of contrivance of the pump kind, which is made uſe of for the purpoſe of detecting

ing and aſcertaining the nature, ſituation, and direction of under-ground ſprings and collections of water, as well as, in ſome meaſure, the nature and poſition of the different ſubſtrata in land, before the work of cutting and forming the drains for taking off the injurious wetneſs is begun. It is conſtructed of copper, in the pipe form, in a very neat, ſimple, and cheap manner, ſo as to admit of being put down into the ground in holes formed by the boring-auger; and by being made to be wrought as a pump, is capable of ſhewing the preſence of water, where the preſſure of it in the higher grounds above is not ſufficient to force it up through the auger-holes, which is the caſe in many inſtances. The nature and direction of the under-ſtrata are, in ſome degree, found in boring and putting the pump down through them. It is the invention and diſcovery of Mr. Wakefield, who has been long much engaged in the practice of draining in ſeveral different places and parts of the kingdom. See Spring-*Draining*.

This is a contrivance which, with the boring-rod, would ſeem to be capable of being of very great importance in the buſineſs of ſpring-draining, as tending, by the facility and certainty which it affords of diſcovering and pointing out the nature, exiſtence, and lines of ſprings, before any thing is done, to prevent a great deal of unneceſſary labour in cutting at random, as has hitherto moſtly been the caſe, and thereby ſave much uſeleſs expence to thoſe who are under the neceſſity of having ſuch works performed. The utility of theſe contrivances is more fully ſhewn under the head alluded to above.

Spring-*Draining Bricks*, the ſeveral different kinds, forms, and ſhapes of bricks which are contrived for this uſe, and which differ from thoſe of the common ſort employed in building purpoſes. They are of many different deſcriptions. Theſe kinds of bricks are moſtly well calculated for forming drains which are to carry off the water coming from ſprings, as a large extent of land may often be rendered dry by no very great quantity of ſuch materials; but they are not ſo well ſuited for drains which are to remove water which ſtagnates on the ſurface of land, though they are occaſionally made uſe of for that purpoſe. They ſometimes form hollow paſſages for the water to run along, as in ſtiff ſoils; but in ſuch as are ſoft they are made to form a ſort of pipe or cylindrical paſſage for the ſame, by being laid one upon the other. See Spring-*Drain*.

Spring-*Bog*, a term applied to that ſort of bog or boggy wetneſs which is cauſed by ſprings, in contradiſtinction to that, or the ſwampy wetneſs, which proceeds from the ſtagnation of rain or other water upon the ſurface of land where theſe prevail in land-locked ſituations.

Spring-bogs are, for the moſt part, more confined than thoſe of the contrary kind, but they are ſometimes equally extenſive with them.

Spring-*Brine*. See Salt-*Brine Spring*.

Spring, *Elater*, in *Phyſics*, denotes a natural faculty, or endeavour, of certain bodies to return to their firſt ſtate, after having been violently put out of the ſame by compreſſing, bending them, or the like.

This faculty philoſophers uſually call *elaſtic force*, or *elaſticity*.

Fleas only jump to exceſſive heights by means of a ſpringy membrane, eaſily viſible by a microſcope; and of which we have a curious figure in Dr. Hooke's Micrographia. By the elaſtic force of this ſpring they are enabled to leap two hundred times the height of their own body. See Flea.

Nature has provided for the regular ſowing of the ſeeds of ſeveral kinds of plants, by furniſhing them with a ſpring, which is wound ſometimes round the outſide, and ſometimes round the inſide of the caſe in which the ſeeds are contained. See Semination.

Spring, in *Mechanics*, is any elaſtic body, commonly of ſteel properly tempered, and formed in various ways, according to the purpoſe it is intended to anſwer, whether it be for giving motion to a machine, or for equalizing and modifying motion derived from ſome other agent. Springs are alſo introduced into inſtruments, called ſpring ſteelyards, for aſcertaining the weights of bodies, as well as having various other applications, which it would be uſeleſs to enumerate in this place.

Conſidering, therefore, the numerous uſes to which this kind of force may be directed, it muſt appear very remarkable that ſo little is known of the true principle of the action of ſprings, and of the laws by which their powers are regulated; we know, indeed, of no regular ſet of experiments, that have yet been made, which are at all adequate to reducing their operation to correct mathematical principles.

Dr. Hooke ſeems to have been the firſt writer who undertook experiments on the action of ſprings, with a view of drawing from them general concluſions, and by this means to introduce them into the theory of rational mechanics: and the reſult which he thus obtained, was his celebrated law "ut tenſio ſic vis," the tenſion is as the force: a law which ſome ſubſequent experimenters have ſtated to be correct, while others of conſiderable eminence have denied its accuracy and agreement with experiment in numerous caſes. The fact, therefore, ſeems to be, that in ſprings of a certain form, and *within certain limits*, the principle is juſt; but that others of different form, and in *all*, when the force is very conſiderable in regard to the ſtrength of the ſpring, it does not apply: and, conſequently, that much ſtill remains to be done before the actions of different ſprings can be admitted to form a part of theoretical mechanics.

Dr. Jurin, by adopting the principle above referred to, *viz.* "the tenſion is as the force," ſucceeded in rendering the action of ſprings ſuſceptible of mathematical computation. See Phil. Tranſ. N° 472. p. 46; or vol. ix. p. 19. of Hutton's Abridgment.

This paper certainly diſplays great ingenuity, and would be of conſiderable utility, provided the hypotheſis there aſſumed were perfectly correct; and even as it is, although a different law may have place between the ſpace through which the ſpring is drawn or compreſſed, and its reſiſtance, the ſame principle of inveſtigation muſt ſtill be preferred; and it may, therefore, be conſidered as the foundation on which the true theory muſt be raiſed, after a ſufficient number of experiments has been made to aſſure us of the correct law of their action, not merely within the narrow limits contemplated by the founder of the hypotheſis, but through all degrees of compreſſion and extenſion, ſhort of that which deſtroys their original elaſticity. We ſhall therefore offer no apology for exhibiting a conciſe view of the principal theorems and deductions of this ingenious author.

Dr. Jurin commences his memoir with a few neceſſary definitions; as the

Length of a ſpring, which is uſed to ſignify the greateſt length to which a ſpring can be forced inwards, or drawn outwards, without prejudice to its elaſticity. He obſerves, this would be the whole length, were the ſpring conſidered as a mathematical line; but in a material ſpring, it is the difference between the whole length, when the ſpring is in its natural ſituation, or the ſituation it will reſt in when not diſturbed by any external force, and the length or ſpace it takes up when wholly compreſſed and cloſed, or when drawn out.

Strength or force of a ſpring is uſed for the leaſt force or weight which, when the ſpring is wholly compreſſed or cloſed, will reſtrain it from unbending itſelf. Hence alſo the force of a ſpring bent, or partly cloſed, is uſed for the leaſt force or weight which, when the ſpring is bent through any ſpace leſs than its whole length, will confine it to the ſtate it is then in, without ſuffering it to unbend any farther.

We have before ſtated, that the principle which this author aſſumes is, that if a ſpring be either compreſſed or ſtretched by any external force, its reſiſtance is proportional to the ſpace by which it is removed from its original and natural ſituation. Thus, ſuppoſe, for inſtance, a ſpring (*Plate* XXXVIII. *Mechanics*, *fig.* 6.) C L, reſting with the end, L, againſt any moveable ſupport, but otherwiſe lying in its natural ſituation, and at full liberty; then, if this ſpring be preſſed inwards by any force, p, or from C towards L, through the ſpace of one inch, and can be there detained by that force, p, the reſiſtance of the ſpring and the force, p, exactly counterbalancing one another; then will the force $2p$ bend the ſpring through the ſpace of two inches, $3p$ through three inches, $4p$ through four inches, &c. The ſpace, C l, (*fig.* 7.) through which the ſpring is bent, or by which its end, C, is removed from its natural ſituation, being always proportional to the force which will bend it ſo far, and will detain it ſo bent.

And if one end, L, be faſtened to an immoveable ſupport (*fig.* 8.), and the other end, C, be drawn outwards to l, and be there detained from returning back by any force, p, the ſpace, C l, through which it is ſo drawn outwards, will be always proportional to the force, p, which is able to detain it in that ſituation.

And the ſame principle holds in all caſes, where the ſpring is of any form whatſoever, and is in any manner whatſoever forcibly removed from its natural ſituation.

It may be here obſerved, that the ſpring, or elaſtic force of the air, is a power of a different nature, and governed by different laws from that of a material ſpring. For ſuppoſing the line L C (*fig.* 6.) to repreſent a cylindrical volume of air, which by compreſſion is reduced to L l (*fig.* 7.), or by dilatation is extended to L l (*fig.* 8.), its elaſtic force will be reciprocally as L l; whereas the force or reſiſtance of a ſpring will be directly as C l.

This principle being premiſed, Dr. Jurin gives us a general theorem concerning the action of a body ſtriking on one end of a ſpring, while the other end is ſuppoſed to reſt againſt an immoveable ſupport. And leſt any objection ſhould be formed againſt the poſſibility of an immoveable ſupport, ſince any body, how great ſoever, may be removed out of its place by the leaſt force, he obſerves, that the objection may be eaſily removed. Thus, if the ſpring L M (*fig.* 9.) be ſuppoſed continued to N, ſo that L N = L M, if a body M, with any velocity in the direction M L, ſtrikes one end of the ſpring, and a body N, at the ſame time, with an equal velocity, and a contrary direction N L, ſtrikes the other end, N, of the continued ſpring, the point L, the end of the firſt ſuppoſed ſpring, will be immoveable.

Theorem.—If a ſpring of the ſtrength P, and the length C L (*fig.* 10.), lying at full liberty on an horizontal plane, reſt with one end, L, againſt an immoveable ſupport; and a body of the weight M, moving with the velocity V, in the direction of the axis of the ſpring, ſtrike directly on the other end, C, and thereby force the ſpring inwards, or bend it through any ſpace C B; and a mean proportional, C G, be taken between the line $\mathrm{CL} \times \frac{\mathrm{M}}{\mathrm{P}}$, and $2a$, a being the height to which a heavy body would aſcend in vacuo, with the velocity V; and upon the radius R = C G, be erected the quadrant of a circle G F A: then,

1. When the ſpring is bent through any right ſine of that quadrant, as C B, the velocity, v, of the body, M, is to the original velocity, V, as the coſine to the radius; that is, $v = \mathrm{V} \times \frac{\mathrm{BF}}{\mathrm{R}}$.

2. The time, t, of bending the ſpring through the ſame ſine C B, is to T, the time of a heavy body's aſcending in vacuo with the velocity V, as the correſponding arc to $2a$; that is, $t = \mathrm{T} \times \frac{\mathrm{GF}}{2a}$.

After demonſtrating this propoſition, the author proceeds to draw from it ſeveral curious corollaries, which, for greater ſimplicity, he divides into three diſtinct claſſes, according as they appertain to the following caſes: *viz.*

Caſe 1.—When the ſpring is bent through its whole length, or is entirely compreſſed or cloſed, before the moving force of the body is deſtroyed and its motion ceaſes.

Caſe 2.—When the moving force of the body is conſumed, and its motion ceaſes before the ſpring is bent through its whole length, or wholly cloſed. And

Caſe 3.—When the moving force of the body is expanded, and its motion ceaſes at the inſtant that the ſpring is bent through its whole length, and is entirely cloſed.

We ſhall enumerate a few of the moſt intereſting corollaries in each of theſe claſſes, premiſing firſt, that P = ſtrength of the ſpring, L = its length, V = the initial velocity of the body cloſing the ſpring, M = its maſs, t = time ſpent by the body in cloſing the ſpring, A = height from which a heavy body will fall in vacuo in a ſecond of time, a = the height to which a body would aſcend in vacuo with the velocity V, C = the velocity gained by the fall, m = the circumference of a circle, whoſe diameter is 1.

Case 1. *Cor.*—When the ſpring is bent through any right ſine, C B, (*fig.* 10.) the loſs of velocity is to the original velocity, as the verſed ſine to the radius; or $\mathrm{V} - v = \mathrm{V} \times \frac{\mathrm{G}g}{\mathrm{R}}$, where v is the preſent, and V the original velocity.

2. When the ſpring is bent through any ſine, C B, the diminution of the ſquare of the velocity is to the ſquare of the original velocity, as the ſquare of the ſine to the ſquare of the radius; that is, $\mathrm{V}^2 - v^2 = \mathrm{V}^2 \times \frac{\mathrm{CB}^2}{\mathrm{R}^2}$.

3. When the ſpring is bent through any ſpace, l, the velocity, v, of the body is equal to $\mathrm{V} \times \sqrt{\frac{2\mathrm{ML}a - \mathrm{P}l^2}{2\mathrm{ML}a}}$, or to $\mathrm{V} \times \sqrt{\frac{2\mathrm{M}a - pl}{2\mathrm{M}a}}$.

4. The time, t, of bending the ſpring through any ſpace, l, is proportional to the arc, G F, divided by $\sqrt{a}$;

l being the right ſine of the arc, and $R = \frac{2MLa}{P}$ being the radius.

CASE 2. *Cor.* 1.—If the motion of the body ceaſe when the ſpring is bent through any ſpace, *l*, the initial velocity is

$$V = Cl\sqrt{\frac{P}{2MLA}}, \text{ or } V = C\sqrt{\frac{pl}{2MA}}.$$

2. If the motion of the body ceaſe when the ſpring is bent through any ſpace *l*, the time, *t*, of bending it is

$$t = 1'' \times \frac{m}{2}\sqrt{\frac{ML}{2PA}}, \text{ or } t = 1'' \times \frac{m}{2}\sqrt{\frac{Ml}{2pA}},$$

where $m = 3.1416$, *viz.* the circumference of a circle to diameter 1.

3. In the ſame caſe, the time of bending the ſpring is proportional to $\sqrt{\frac{ML}{P}}$, or to $\sqrt{\frac{Ml}{p}}$; and if $\frac{L}{P}$ be given, *t* will be as $\sqrt{M}$; and if both $\frac{L}{P}$ and M be given, *t* will always be the ſame, whatever be the original velocity, or through whatever ſpace the ſpring is bent.

4. If the motion of the body ceaſe when the ſpring is bent through any ſpace, *l*, the product of the initial velocity, and the time of bending the ſpring, or V *t*, = $1'' \times \frac{mCl}{4A}$, and is proportional to *l*, the ſpace through which the ſpring is bent.

Hence, any two of the three quantities, V, *t*, and *l*, being given, the other is readily determined.

5. In the ſame caſe the initial quantity of motion M V $= Cl\sqrt{\frac{PM}{2LA}}$, or $MV = C\sqrt{\frac{plM}{2A}}$.

CASE 3. *Cor.* 1.—If the motion of the body ſtriking the ſpring ceaſe, when it is wholly cloſed, the initial velocity $V = C\sqrt{\frac{PL}{2MA}}$.

2. The initial velocity V is proportional to $\sqrt{\frac{PL}{M}}$.

3. If P L be given, either in the ſame or in different ſprings, the initial velocity V is reciprocally as $\sqrt{M}$.

4. The product of the initial velocity, and the time ſpent in cloſing the ſpring, or V *t*, = $1'' \times \frac{mCL}{4A}$; and is proportional to L, the length of the ſpring.

5. The initial quantity of motion, or M V, = $C\sqrt{\frac{PLM}{2A}}$.

6. M V is proportional to $\sqrt{PLM}$, or to P *t*. And if P L be given, either in the ſame or different ſprings, M V is as $\sqrt{M}$.

7. If $\frac{P}{L}$ be given, either in the ſame or in different ſprings, the initial quantity of motion is as the length of the ſpring into the time of bending it.

8. If a quantity of motion, M V, bend a ſpring through its whole length, and be conſumed by it, no other quantity of motion equal to the former, as $nM \times \frac{V}{n}$, will cloſe the ſame ſpring, and be wholly conſumed by it.

9. But a quantity of motion, leſs or greater than M V, in any given ratio, may cloſe the ſame ſpring, and be wholly conſumed in cloſing it; and the time ſpent in cloſing the ſpring will be reſpectively leſs or greater, in the ſame given ratio.

10. The initial *vis viva*, or MV^2, $= \frac{C^2PL}{2A}$; and $2aM = PL$.

11. The initial *vis viva* is as the rectangle under the ſtrength and length of the ſpring: that is, MV^2 is as P L.

12. If $\frac{P}{L}$ be given, the initial *vis viva* is as P^2, or as L^2.

13. If the *vis viva* MV^2 bend a ſpring through its whole length, and be conſumed in cloſing it; any other *vis viva*, equal to the former, as $n^2M \times \frac{V^2}{n^2}$, will cloſe the ſame ſpring and be conſumed by it.

14. But the time of cloſing the ſpring by this *vis viva* $n^2M \times \frac{V^2}{n^2}$, will be to the time of cloſing it by the *vis viva* MV^2, as *n* to 1.

15. If the *vis viva* MV^2 be wholly conſumed in cloſing a ſpring of the ſtrength P, and length L; then the *vis viva* n^2MV^2 will be ſufficient to cloſe, 1, either a ſpring of the ſtrength n^2P, and length L; 2, or a ſpring of the ſtrength *n* P, and length *n* L; 3, or of the ſtrength P, and length n^2 L: 4, or if *n* be a whole number, the number n^2 of ſprings, each of the ſtrength P, and length L, one after another. We may add, that it appears from hence, that the number of ſimilar and equal ſprings a given body in motion can wholly cloſe, is always proportional to the ſquares of the velocity of that body. And it is from this principle that the chief argument, to prove the force of a body in motion to be as the ſquare of its velocity, is deduced. See FORCE.

The theorem above-mentioned, and its corollaries, will hold equally, if the ſpring be ſuppoſed to have been at firſt bent through a certain ſpace, and by unbending itſelf to preſs upon a body at reſt, and thereby to drive that body before it, during the time of its expanſion: only V, inſtead of being the initial velocity with which the body ſtruck the ſpring, will now be the final velocity with which the body parts from the ſpring, when totally expanded.

It is alſo to be obſerved, that the theorem, &c. will hold equally good, if the ſpring, inſtead of being preſſed inwards, be drawn outwards by the action of the body. The like may be ſaid, if the ſpring be ſuppoſed to have been already drawn outwards to a certain length, and in reſtoring itſelf draw the body after it. And, laſtly, the theorem extends to a ſpring of any form whatever, provided L be the greateſt length it can be extended to from its natural ſituation, and P the force which will confine it to that length. See Phil. Tranſ. N° 472. ſect. 10. or vol. xliii. art. 10.

SPRING is more particularly uſed, in the *Mechanic Arts*, for a piece of tempered ſteel, put into ſeveral machines to give them motion, by the endeavour it makes to unbend itſelf.

In watches it is a fine piece of well-beaten ſteel, coiled up in a cylindrical caſe, or frame; which, by ſtretching itſelf forth, puts the wheels, and the whole movement, in motion. See Fusee, and Watch.

The ſpring of a watch is prepared by forming a very thin plate of ſteel into a double ring, bending it round with wire, and putting it into a proper furnace, in order to give it a ſuitable degree of heat. When that is acquired, it is taken out, and dropped into a kettle of oil, or warm mutton ſuet, in conſequence of which proceſs it poſſeſſes a degree of hardneſs, very little inferior to that of glaſs. After this it is reduced or let down, if the ſteel be of a proper kind for the purpoſe, to a fine violet or blue colour; in which ſtate it becomes exceedingly elaſtic, inſomuch, that to make it ſtand bent, it muſt be brought into a very acute curve; nor can it eaſily be brought, by twiſting horizontally, to alter its form, without endangering its being broken to pieces. But as it afterwards requires to be planiſhed by the hammer, filed, and poliſhed, it is again deprived in a conſiderable degree of its elaſticity: and, therefore, when it has received its laſt poliſh, it muſt again be blued upon a braſs plate over a lamp, by which means its former elaſticity is perfectly reſtored. Dr. Hooke, in his Micrographia, ſays, that this blue covering is owing to the fine ſulphur, preſſed through the pores by heat, and fixed by the ambient air in a fine vitrified lamina upon the ſurface. See Steel.

The ſpring of a lock, piſtol, or the like, is a piece of ſteel violently bent, which beats back the bolt, or ſtrikes down the cock, when ſet at liberty.

Spring-*Arbor*, in a *Watch*, that part in the middle of the ſpring-box, about which the ſpring is wound or turned, and to which it is hooked at one end.

Spring-*Box*, the cylindrical caſe, or frame, that contains within it the ſpring of the watch.

Spring-*Compaſſes*. See Compasses.

Spring-*Rings*, in *Rural Economy*, the large ring contrivances of the ſtrong ſpring kind, through which the reins paſs in ſtables, in order to prevent horſes from being injured by being entangled in them. They have a different form from the rings which are commonly employed, and are fixed in an immoveable manner to the ſtems, ſhanks, or parts, which ſcrew into the wood and hold them faſt. The ſprings in them are ſo contrived, as that the reins of the head-ſtalls can be ſlipped into and out of them with great eaſe and facility. They are a very uſeful and ſafe ſort of ring contrivance, for this purpoſe, in many caſes, eſpecially where horſes are reſtleſs, and much liable to the above kind of accidents. The expence of them is not great, while the ſecurity which they may afford is conſiderable. They are equally neceſſary and beneficial in farm ſtables as thoſe of the ſaddle-horſe kind. See Stable *Rings for Stalls*.

Spring *of the Air*, or its elaſtic force. See Air and Elasticity.

Spring, in a *Ship*, is a rope paſſed out of one extremity of a ſhip, and attached to a cable proceeding from the other, when ſhe lies at anchor. It is uſually performed to bring the ſhip's broadſide, or battery of cannon, to bear upon ſome diſtant object: as another ſhip, or a fortreſs on the coaſt, &c.

Spring is likewiſe a rope reaching diagonally from the ſtern of a ſhip to the head of another, which lies alongſide or abreaſt of her, at a ſhort diſtance. This is generally performed to make one of the ſhips ſheer off to a greater diſtance from the other; or to make merchant-ſhips lie uniformly in the ſame tier. Springs of this ſort are, therefore, occaſionally applied from a ſhip to a wharf or key, for the ſame purpoſe. Falconer.

Spring *a Leak, To.* See Leak.

Spring *the Luff, To.* See Loof.

Spring *a Maſt.* See Mast.

Spring, *To*, in *Military Language*, is to give vent to any combuſtible matter upon which gunpowder principally acts by the power of exploſion. Hence the phraſe to ſpring globes of compreſſion, &c. which are frequently uſed for the ſame purpoſes with ſky-rockets, &c. to ſerve as ſignals when any ſudden attack is to be made.

Spring, *To*, is alſo to ſtep forward with a certain degree of elaſticity.

Spring *the Firelock, To*, is to bring it briſkly up to any ordered poſition, *e. g.* in the recover.

Spring *Up*, a word of command occaſionally uſed, and ſignifying the ſame as double up; ſometimes uſed ſingly, as *ſpring!* particularly to light infantry men.

Spring, *Cear*. The cear is a piece of hardened iron or ſteel in a gun-lock, which moves on a pivot, and the point of which is received in a notch cut in the tumbler, and the other end is acted upon by the trigger. The cear ſpring is a ſmall ſpring, which throws the cear into the ſaid notch, when the piece is at half cock or full cock.

Spring, *Feather*, the ſpring of a gun-lock beneath the foot of the hammer, called likewiſe hammer-ſpring.

Spring, *Main*, the ſpring of a gun-lock, which operates on the tumbler, and gives force to the cock.

Spring, *Ver*, in *Coſmography*, denotes one of the ſeaſons of the year; commencing, in the northern parts of the world, on the day the ſun enters the firſt degree of Aries, which is about the twenty-firſt day of March, and ending when the ſun leaves Gemini.

Or, more ſtrictly and generally, the ſpring begins on the day when the diſtance of the ſun's meridian altitude from the zenith, being on the increaſing hand, is at a medium between the greateſt and leaſt. The end of the ſpring coincides with the beginning of ſummer.

Spring is the ſeaſon in which plants vegetate and grow with the moſt force and luxuriance. Late ſprings are, however, in general, the moſt beneficial to the farmer, and occaſionally to the gardener.

In ſuch ſprings as are late in their appearance, there is, for the moſt part, leſs danger in the climate of this country of the crops of different kinds ſuffering from the checks and injuries which they may receive in them, than in thoſe which are early, as the changes in them are moſtly much leſs frequent, and at the ſame time much leſs ſevere.

Fruit-trees of various kinds are often greatly injured in the formation and production of their fruit by early ſprings. This is particularly the caſe with the almond, the apple, the plum, and the cherry-tree, as well as with the gooſeberry-buſh, and ſome others. The peach, the nectarine, and ſome other fine fruited trees, are alſo ſometimes much injured in their fruiting by early ſprings, as where they are planted againſt walls or palings, in the open ground in expoſed ſituations.

Garden-crops of many different kinds not unfrequently ſuffer greatly from early ſprings; whole crops of particular ſorts being, in ſome inſtances, nearly deſtroyed, as is not ſeldom the caſe, in ſuch ſeaſons, in the firſt ſown onion, pea, and ſeveral other kinds of culinary crops.

Spring *Crops*, in *Agriculture*, ſuch as are put into the ground in the ſpring ſeaſon of the year, as oats, barley, ſome ſorts of wheat, and different other crops. See theſe heads.

Spring *Food*, that ſort of food, whether of the turnip, rye, tare, rape, cabbage, preſerved graſs, artificial graſs, natural graſs, or any other kind, which is made uſe of for live-ſtock, eſpecially ſheep, in the ſpring ſeaſon.

Spring *Garden*, that ſort of ornamental garden which is chiefly deſigned for the introduction of all ſorts of curious early budding and flowering trees, ſhrubs, and flower-plants, in the intention of affording beauty, variety, and effect.

Gardens of this nature ſhould be ſuitably ſituated ſomewhat contiguous to thoſe of the winter kind, being connected with them and the reſidences by ſuitable walks of the gravel kind, ſo as that they may be gone into at any ſeaſon or period without inconvenience. The ground or ſoil for them ſhould be of the more light, friable, and dry kind, and be ſo ſituated as to be well expoſed to the influence of the ſun, being completely ſheltered on the northern ſides, ſo as to prevent the blaſts from that quarter having any injurious effects on them. They ſhould alſo have ſome ſort of neat ornamental erection in them for containing the heaths, the auriculas, and different other tender early flowering plants.

Gardens of this ſort have a fine effect in many ſituations, when well laid out and managed. See Parterre.

Spring *Graſs*, a term ſometimes applied to the ſweet-ſcented vernal or meadow-graſs, from its being ſo forward or early in its growth. See Anthoxanthum *odoratum*.

It alſo ſignifies the graſs of any kind that ſprings early in the ſpring ſeaſon, and which affords the firſt bite for live-ſtock of any ſort.

Spring *Sowing*, ſuch ſowings as are performed in the ſpring ſeaſon, as that for ſpring wheat, oats, barley, and many other crops. See Sowing *of Seeds*.

Spring *Sowing*, in *Gardening*, comprehends all thoſe ſowings which are made at that ſeaſon of the year, eſpecially for any ſort of general ſeed crops, as thoſe of the pea, bean, and ſmall ſeed kinds. Small flower and other ſeeds are put into the ground at an early period with advantage, as they are much leſs liable to be injured by inſects in their after-growth, and riſe more favourably than where the contrary is the caſe. The ſame is ſometimes the caſe with ſmall graſs ſeeds ſown in the field. See Sowing *of Seeds*.

Spring *Tare*, a term uſed to ſignify that ſort of tender tare, which is ſown and cultivated in the ſpring ſeaſon for ſummer uſe, in contradiſtinction to the winter tare, which is uſually ſown in the autumn, and ſtands the ſeverity of the winter ſeaſon. See Tare.

Spring *Tide* is the increaſing of a tide after a dead neap; or the periodical exceſs of the elevation and depreſſion of the *tide;* which ſee.

Spring *Wheat*, that ſort of this kind of grain, which is capable of being ſown or put into the ground in the early ſpring ſeaſon, and cultivated or grown with the ſame or greater ſucceſs and advantage, than the common kind. It has been ſtated by ſir Joſeph Banks, that real ſpring wheat, the *triticum æſtivum*, or ſummer wheat of the botaniſts, is a grain too tender to ſtand and bear the froſts of the winter in this climate, but as quick in its progreſs from its firſt ſhoot to ripeneſs, as barley, oats, or any other ſpring corn. See Triticum.

The writer of the tract on the reſult of an Inquiry into the nature and cauſes of the blight, the ruſt, and the mildew, which have affected the wheat-crops on the borders of England and Scotland, has ſuggeſted, that common or winter wheat requires the moſt expenſive culture, being generally put into the ground in the autumn, and uſually requiring eleven months before it arrives at maturity; that conſequently the returns from ſuch a ſpecies or ſort of grain, ſhould be more lucrative than when ſpring corn of this kind is raiſed, which, after remaining only about four months in and on the ground, is then in a proper ſtate to be cut down. Nor is the difference in point of produce ſuppoſed to be ſo very material, as to render it indiſpenſably neceſſary to excluſively cultivate winter wheat, with a view to profit; and, indeed, it would appear, it is ſaid, that in ſeveral other reſpects, it would be deſirable to grow a conſiderable quantity of ſpring wheat in this kingdom, as being better calculated for the different ſoils and ſituations in different parts and places, as being leſs liable to diſeaſe, and as furniſhing a moſt important reſource in caſe there be reaſon to apprehend that the autumn or winter-ſown wheats may become unproductive, or of a bad quality.

It is well known, that in ſome parts of the kingdom it is the practice to ſow winter wheat in the ſpring, ſeldom, however, it is ſuppoſed, later than the month of February, or the middle of March, and have occaſionally good crops from it; and it is underſtood, from the moſt reſpectable authority, that though the winter wheat ſown in the ſpring is at firſt later in ripening than the ſame ſort ſown in autumn, yet that this diſadvantage, in regard to becoming ripe, leſſens, when the crop of wheat of that ſort which was ſown in the ſpring, is ſown again in the ſucceeding ſpring. Winter wheat ſown in ſpring thence acquires a tendency, it is ſaid, to earlier maturity, if reſown in the ſpring; but from an experiment which was tried in the county of Middleſex, it does not appear, that when ſown in the autumn it becomes ripe earlier than common winter wheat. But ſtill, it is admitted, that it does not ripen quite ſo ſoon as wheat ſown in autumn, nor as real ſpring wheat, nor can it be ſown ſo late in the ſeaſon. An intelligent farmer, it is ſaid, ſtates the difference between real ſpring wheat and winter ſpring-ſown wheat, at three weeks; which is a moſt material advantage in favour of the former. But as we have a ſpecies or ſort of wheat which is peculiarly calculated for ſpring culture, why, it is aſked, ſhould we endeavour to force another ſort to alter its nature and properties, and to grow and acquire maturity in a ſhorter] period of time than nature intended? And if conſiderable quantities of wheat too can be ſown in the ſpring, with perfect ſafety and ſucceſs, why, it is alſo aſked, ſhould we confine our Lent or ſpring crops of grains to oats and barley? It is ſuggeſted, as being alſo underſtood by the ſame writer, on reſpectable authority, that the ſpring-ſown wheats were, at one time, getting out of uſe or faſhion in France; but that they were ſoon under the neceſſity of again returning to them as an eſſential ſource of ſupply.

In this place we may then ſhortly conſider the hiſtory, nature, qualities, uſes, and advantages of it, as well as the ſorts of land and expoſures moſt ſuited to its growth, and the means by which the ſeed of it may be the beſt and moſt readily procured; leaving the methods of its cultivation, growth, application, and other points and circumſtances, to the head wheat, to which indeed they as well as it properly belong. See Wheat.

Spring, or this ſort of wheat, is ſuppoſed, and with great probability, to have been originally produced in Sicily, where it is known, it is ſaid, under the name of *Tumenia*, a corruption of *Trimenia*, or three months' grain. It is alſo much cultivated in Barbary, in Spain, in Portugal, in France, in Germany, and in almoſt all the corn countries, with the exception of this country, where, on account of the immenſe conſumption of malt-liquors, barley is more in demand, than where wine is the common beverage of the people. The former of the above writers conſiders it as well known over all parts of the continent of Europe, and to be much uſed and employed in cultivation in France, where it is called *Blé de Mars*, from the ſeaſon in which it is uſually ſown; and in ſome provinces of that tract of country *Bleds-tremois*, from the time it takes between ſeed-time and harveſt; that in Spain, it is called *Trigo de Marzo;* in Portugal, *Trigo Tremes;* and in Germany, *Sommer Whaitzen;* according to the languages of the different countries; all of which names are ſaid to mark in a diſtinct manner the difference between this and the winter corn of the ſame ſort. It has alſo been aſſerted on the ſame authority, that ſpring wheat may be ſown in autumn, and that if it ſhould ſucceed, it will produce a beautiful ſample, but that as it is, like barley, a tender plant, a ſevere froſt will kill it. Some have, however, ſuppoſed it to be a native of ſome part of Tartary, but it is evidently the production of a warm climate, ſuch as that noticed above. It has been claſſed by Ray, and probably others, as a diſtinct ſpecies or ſort of wheat. In regard to its introduction into this country, it is commonly believed to have been introduced or brought into it about the year 1773, or probably a little earlier, under the names of Siberian wheat, Switzerland wheat, or blé de Mars, as above. It is ſaid, however, to have been mentioned by Harriſon, an hiſtorian in the time of Elizabeth, though he repreſents it as having been then only known to a few huſbandmen or farmers.

It has alſo been ſaid that ſpring wheat was known to the Romans as a ſpecies or ſort diſtinct from the common autumn or winter kind, and deſcribed as ſuch by Columella, who conſidered and believed it very acceptable to the farmer, when, in conſequence of floods, rains, or other ſimilar cauſes, the autumn or winter wheat was prevented from being ſown or put into the ground by him. And that the Rev. Mr. Dickſon, in his "Huſbandry of the Ancients," has likewiſe conſidered it as well adapted to the wet cold climate of Scotland, where, on account of heavy rains, and other cauſes, the farmers are not unfrequently reſtricted in regard to the quantity of autumn or winter wheat that can be ſown or got into the ground.

The writer firſt noticed has, however, remarked, that it does not appear from the older books on huſbandry, that it was at any former period much grown or cultivated in this country; and that the more modern ones are in general ſilent on the ſubject of it: they mention, indeed, under the name of ſpring wheat, every kind of winter wheat which will ripen when ſown after turnips in the month of February; but little or nothing is ſaid on real ſpring wheat. This, it is conceived, is probably the reaſon why the real ſpring wheat has been ſo little known, the cultivators of land in general conceiving themſelves to be actually in the habit of ſowing ſpring wheat, when, in reality, they were only ſubſtituting winter wheat in its place, have been little inclined to inquire into the properties or qualities of the real ſpring wheat, when they had an opportunity and the means of ſo doing.

The inquirer already noticed ſtates, on the authority of an intelligent correſpondent, that above thirty years ago, the empreſs Catharine ſent a buſhel of ſpring wheat to his majeſty, which the king gave to Mr. Ducket, the celebrated farmer of Eſher, in the county of Surrey, who cultivated it for ſome time, and ſold a number of buſhels from it for ſeed. Notwithſtanding which, not a veſtige of it now, it is ſaid, remains in all that neighbourhood. On which, it may be obſerved, that, as coming from Ruſſia, it might not be the beſt ſort of ſpring wheat, of which there are ſo many varieties, as will be ſeen below: that a ſmall quantity, thus accidentally introduced into a diſtrict, might get into improper hands, and be given up from thoughtleſſneſs or inattention: that the difference of price between wheat and barley, conſidering the difference of produce, was then ſo inconſiderable, as to induce farmers to give up the culture, not only of ſpring, but even of winter wheat: and that the introduction of many other uſeful objects and practices, beſides that of ſpring wheat, has at firſt many obſtacles, difficulties, and impediments to contend with. The late Dr. Walker, in a work noticed below, has likewiſe obſerved that this ſort of wheat, or the true *ſummer* wheat, as he calls it, is a grain very little known in this country, though much grown in the northern parts of France, as well as in Jerſey, Guernſey, and in other places. It was firſt brought into Ayrſhire, in Scotland, from the iſland of Jerſey, by John, earl of Loudoun, during ſpring, in the year 1766. And that, on being ſown in a heavy clayey ſoil, and upon one of a more early kind, in the former on the 7th of April, and in the latter on the 4th of the ſame month, it was reaped or cut down on the 26th of September in the firſt caſe, and on the 4th of the ſame month in the laſt. In both inſtances, it afforded ten Linlithgow bolls of wheat, which are above forty Wincheſter buſhels, upon the Scotch acre. When the grain was weighed, a boll of it was found to be only two pounds lighter or leſs than a boll of winter wheat.

Spring wheat of the true kind, though ſown ſo late as near the middle of May, has been found to become ripe at the ſame time with the autumnal or winter wheat, and that there is no benefit gained by early ſowing with it, as that which has been put into the ground in April, has become ripe as early as that ſown in the beginning of the preceding month. In its growth, it is ſaid by ſome that it does not tiller in the manner of common or winter wheat, but ſhoots up and advances immediately and directly from the moment of its appearance above the ſurface of the ground. The grains or corns, which are ſmaller than thoſe of the common winter wheat, become larger and finer by being grown on better and more fertile land. It is ſuppoſed to ſucceed well on low fenny ſorts of land, which are apt to be flooded during the winter ſeaſon: and that it is highly deſerving of being tried in the mountainous parts of Derbyſhire, Yorkſhire, Lancaſhire, and ſome other northern diſtricts, where little or no wheat is ſown, the ſituations and expoſures being too cold and open for wheat ſown in the autumn to ſtand the ſeverity of the winter froſts, thaws, and rains, without periſhing and being deſtroyed. It has been noticed, that though, under particular circumſtances, ſpring wheat, when lately tried, has not always anſwered perfectly well, yet that in many caſes it has ſucceeded to a wiſh, and that it is now the prevailing huſbandry in an extenſive diſtrict in the county of Lincoln: that the growth of wheat has become more important and eſſential than ever, ſince it has become ſo much more generally uſed as food: and that the price now ſo much better and more fully rewards the induſtry of the grower or huſbandman. All theſe circumſtances being taken into full conſideration, no ſubſtantial reaſon can, it is thought, be aſſigned, why ſpring wheat ſhould not be raiſed in every diſtrict of this country which is calculated for the growth and cultivation of ſo important a national reſource in this ſort of grain, and without the poſſeſſion of which, it is indeed thought that this country cannot be permanently independent of foreign ſupply.

The writer of the above Inquiry ſtates, that there are, it is ſaid, about fifty varieties of ſpring, or this ſort of wheat; but that the kind or variety beſt known in this country has awns like barley, and hence that it is ſometimes known under the name of *rough* or *bearded* wheat. The pickle or grain in it is red; but it has not ſo bold or full a ſample as winter wheat, yet it weighs better; it is conſequently preferred by all honeſt millers, who know its nature and value, as the perſons engaged in this buſineſs are now moſtly beginning to do. Some farmers mix it with different proportions of winter red wheat, as the red Lammas, which reſembles it ſo much in colour, that they never fail to profit by the practice, as it increaſes the weight of the mixture more than it diminiſhes the quality of the ſample; and beſides renders it more productive at the mill. The proportions employed are uſually about one half, or rather leſs than that quantity, in ſuch mixtures. The average weight of ſpring wheat is moſtly about ſixty pounds the buſhel. The bread made from the flour of it is, it is ſaid, ſweeter than that from winter corn of the wheat kind. And that it is likewiſe more nutritious, as containing a larger proportion of gluten, or half animalized matter, in its compoſition. The bread is alſo allowed to be more palatable, it is ſaid, to thoſe who are in the habit of conſtantly eating it. In proof of its greater power of nouriſhment and ſupport, the analyſis of ſir Humphrey Davy has ſhewn, that it has more gluten or real nutrient matter in it, when compared with other grains of the ſame kind, than in good winter wheat, in the proportion of twenty-four to nineteen in the hundred. And that in regard to the inſoluble matter or part, or the bran, there is only a difference of two parts more in the hundred, when compared with good winter wheat of this country. Conſequently, that the difference in price between it and ſuch wheat, when of equal weight, ſhould only be in that proportion.

The advantages which attend the more general introduction and growth of this ſort of grain or wheat, are partly of a private, and partly of a public nature. In the former point of view it is of great importance, it is ſaid by the writer of the above inquiry, to have it in the power of the farmer to raiſe ſo valuable an article as wheat, though ſown late in the ſpring, or even in the beginning of ſummer. It was formerly generally conceived that after turnips, which was conſidered as the baſis of good huſbandry on light ſorts of land, that barley, including bear or bigg, was almoſt the only crop that could be raiſed and grown with advantage, as the ſowing of winter wheat in the ſpring could only be attempted or practiſed in a partial manner. But it now appears that ſpring wheat may be raiſed and grown with as much eaſe and facility, and with more profit, than the inferior ſorts of barley, too great a quantity of which is grown at preſent, ſince the exportation of grain has been cheecked and reſtricted, and ſuch enormous duties laid on malt. But here is a reſource, it is ſaid, which, if aided by a prohibition of foreign wheat from being imported, unleſs at augmented rates or prices, would always enable the farmer or grower, where his ſituation and the nature of his land are ſuited to the cultivation of it, to proceed in his uſeful and induſtrious career with proper inducement, energy, and ſpirit.

A ſtill further moſt important circumſtance in favour of ſpring wheat is, that, it is ſaid, of its not only being exempt from the blight or mildew, but alſo of its not being liable to any riſk of damage or injury from the grub or wire-worm: and this is a matter which is not to be attributed to the nature of lands or ſeaſons; for the farmers of the extenſive tract or diſtrict of country known by the name of South Holland, in the county of Lincoln, in which there are various kinds of land, uniformly declare, that they were compelled, many years ago, by the frequent attacks of the blight and mildew, to abandon almoſt entirely the ſowing of winter wheat, and to ſubſtitute ſpring wheat in its place or ſtead. That ſpring wheat is not liable to the diſeaſe of blight or mildew, has alſo been lately ſhewn by a field of twelve acres, which was totally, it is ſaid, exempt from that diſeaſe, in a diſtrict where every other field was in a moſt miſerable ſtate or condition with it. In the corrected account of the "Agriculture of the County of Eſſex," it is ſtated, however, that there is an inſtance of ſpring wheat being mildewed: and that Mr. Bailey, of Chillingham, ſtates, in a letter to the writer of the "Inquiry," that ſpring wheat, ſown in the month of March, was affected with the mildew, while the ſame ſort, ſown on the 2d, the 3d, and the 10th of May, eſcaped; alſo, that ſome ſpring or bearded wheat of the laſt crop, ſuffered from that diſorder where it was thick on the ground, probably owing to the want of air; for where it was thin, it eſcaped. The writer of the "Inquiry," however, conceives, that a few exceptions cannot overturn a general rule, which was recognized above a century ago in the "Syſtema Agriculturæ," printed in the year 1681, and which repeated experience has ſince ſanctioned. They, however, ſufficiently prove that it is not wholly incapable of receiving the diſeaſe under particular circumſtances and modes of growth. The authority of the work quoted is probably of no great conſequence, as real ſpring wheat was at that early period but little if at all known or cultivated in this country. The fact or matter can perhaps only be ſatisfactorily aſcertained and decided by more full and correct experimental trials than any which have hitherto been made. It is a very material point in its favour, however, that it is a vaſt deal leſs liable to the diſeaſe than autumnal or winter wheat, which is allowed on all hands.

It ſhould, however, be noticed, that it is liable, as in the other kind of wheat, to be affected with the ſmut, and conſequently that it muſt be carefully waſhed, brined, or pickled, in order to avoid any riſk of the diſeaſe, with a very highly ſaturated ſolution of common ſalt, in ſuch a manner as to prevent the danger of this ſort of infection being communicated in any way, and then duſted over with quicklime, as has been occaſionally practiſed, and as will be more fully ſhewn in ſpeaking of ſteeps and ſteeping grain. See STEEP, and STEEPING *Grain*. See alſo SMUT.

In the latter of the above points of view, the advantages of raiſing this ſort of wheat are not leſs important. The writer of the "Inquiry" ſtates, that for ſeveral years paſt we have depended on importation for a part of our food. We have ſent abroad, it is ſaid, above thirty millions ſterling, to enrich and improve foreign countries, the moſt part of them lately in a ſtate of hoſtility againſt us; and that ſo regular were our demands, that they were led to imagine that we could not exiſt without their aſſiſtance in this way. What, therefore, can, it is aſked, be more deſirable than to put an end to ſuch a diſgraceful dependence upon ſuch nations, which, by the growth and cultivation of ſpring wheat to a conſiderable and ſufficient extent, may at once be completely and effectually accompliſhed? It ſeems to the writer, indeed, of ſuch eſſential importance, that until the ſyſtem or practice is thoroughly eſtabiſhed, ſome legiſlative encouragement, to increaſe the growth and cultivation of this ſort of wheat, would be in the higheſt degree expedient. How much better, it is ſaid, is it to promote domeſtic cultivation and improvement, than to beſtow bounties on the importation of mere traſh, the refuſe of foreign granaries, of which ſuch quantities are commonly ſent to this country in times of ſcarcity?

It may conſequently be fairly aſked, whether the cultivation and growth of ſpring wheat ſhould not be conſidered as a national reſource of very great magnitude and importance; and as ſuch be ſtrongly inculcated on, and recommended to, the attention of the public? The utility and conſequence of it in this way, in times off carcity, have indeed been enforced by the firſt of the above writers and others, by obſerving that the price of wheat ſeldom advances much, even in very ſcarce years, until a conſiderable portion of the crop has been threſhed out, and the yield of it by this means aſcertained, but that this does not take place until the ſeed-time of winter wheat is wholly over and paſt; no ſpeculation, conſequently, of ſowing an increaſed quantity of that grain, can be entered into, during the firſt year of a ſcarcity; but before the end of April, the queſtion of the average yield of the preceding crop will be generally known, and when it is much below the uſual proportion, there can, it is ſuppoſed, be no doubt, that a large quantity of ſpring wheat will be ſown, if the ſeed can be *eaſily* procured. And that when there is, in the early ſpring months, any general appearance of defect or deficiency in the autumnal ſown crops, from whatever cauſe it may ariſe, ſpring wheat ought to be ſown, in ſuch proportion as may ſuffice for yielding a produce equivalent to ſuch probable defect or deficiency: and that if the ſtock of wheat on hand ſhould prove ſcanty, or of inferior quality, either from mildew or other cauſes, there is, on theſe accounts, a neceſſity to have recourſe to the ſowing of ſpring wheat, in order to augment and increaſe the ſtock on hand. It is thought more eſpecially neceſſary by the writer of the "Inquiry," to promote the cultivation and growth of ſpring wheat in a more general manner, becauſe, unleſs it be grown to ſome extent, no quantity of ſeed will be capable of being procured, however neceſſary it may become from the circumſtances of the times, as for inſtance, a complete failure of the winter-ſown wheat, at once to increaſe the quantity that is to be ſown. And that though ſpring wheat may not be ſo ſaleable, in favourable ſeaſons, as winter wheat, at leaſt in the metropolis, and its immediate neighbourhood; yet as it can be raiſed in various parts of the country, where winter wheat will not grow; and as it may be applied to different uſeful purpoſes beſides the article of bread; there is no reaſon, it is ſuppoſed, why the cultivation of it ſhould not be promoted. It is always a reſource which can be reſorted to in times of ſcarcity, with much more advantage to the country than importing foreign grain, to the diſgrace, and it might almoſt be added, it is ſaid, to the deſtruction of the agriculture of this country. There are ſome, however, who think foreign wheats more valuable and uſeful than thoſe of this country, as will be ſeen in ſpeaking of wheat. See WHEAT.

It is ſaid, that it has been objected to the grain of this ſort of ſpring wheat, that it is of a hard and flinty quality; but that our millers find no difficulty in grinding it; and it is well known, that the harder and more flinty the pickle, the better and livelier is the flour. The moſt flinty wheat, it is remarked, may be ground with facility, when properly damped. And that the French, when in Egypt, were taught by the millers there, to ſuffer their wheat to ſteep a few hours in water, and the grain, when afterwards dried in the ſun, was ground without difficulty. In this country, it is ſuggeſted that it might be kiln dried, or otherwiſe, perhaps, by fire heat.

The ſame writer obſerves, it is alſo ſaid, that barley is a ſafer crop, and that oats would be more profitable. In regard to ſafety, no crop, it is ſaid, can be more certain than ſpring wheat, when it is ſown in a proper ſeaſon, with good, well waſhed, or pickled ſeed, in the manner already ſtated, and on land properly prepared for its reception; and as to profit, were a crop of oats to be equally, or even more valuable, which is far from being the caſe, yet ſuch a ſcourger or exhauſter of the ground could not be recommended, in preference to a crop that does not exhauſt or deteriorate the land more than barley would; and yet, if other crops of wheat ſhould fail, would be much more valuable and uſeful.

In the metropolis, however, it is ſaid, where they are accuſtomed to the fineſt wheats, and where faſhion and habit render it neceſſary to make the bread as white as poſſible, this kind of wheat is objected to as coarſe, thick-ſkinned, and as producing clammy flour. It conſequently finds no favour with the millers in the neighbourhood of that great city, who, it is ſaid, in times of ſcarcity, would only buy it in ſmall quantities, at a price two-thirds lower than that of the common ſorts; and in years of medium produce, would not purchaſe it, in quantities, at almoſt any price. This, however, it is ſaid, is altogether owing to the prejudices and habits of a rich and luxurious capital, and will not probably influence the reſt of the kingdom. Beſides, if it be thought eſſential for the public intereſt always to have a conſiderable quantity of this ſpecies or ſort of corn grown in this country as a *national* reſource, the policy of which, it is thought, would ſeem unqueſtionable, government might in various ways promote the ſale of this ſpring ſort of wheat; as, by permitting the exportation of it, when the price is ten ſhillings the quarter leſs than that of other wheat; by reſtricting the manufacture of ſtarch to the uſe of it, if it can be employed in that way; by permitting the conſumption of this ſort of wheat in the diſtilleries, while a prohibition exiſts as to other wheats; by making all the biſcuits for the navy of it alone, as it ſeems peculiarly well ſuited for that uſe; and probably by different other means.

It is ſtated, it is ſaid, that theſe advantages cannot be given to ſpring wheat, becauſe it is impoſſible to diſtinguiſh it from coarſe or partially mildewed winter wheat; but ſome riſk muſt be run, the writer thinks, to inſure ſo great a public object and advantage as a regular ſupply of food by *domeſtic* induſtry. And if ſome low-priced or damaged winter wheats were mixed with ſpring wheat, and exported, diſtilled, or made into ſtarch, it is not ſeen that any injury or inconvenience from ſuch a circumſtance would be ſuſtained by the public. It is better, it is ſuppoſed, except in inſtances of dearth and ſcarcity, to get rid of inferior wheats in any way, than in bread.

In regard to the ſorts of land, and the ſituations in which this ſort of wheat can be produced, it has been found, that almoſt all the kinds, from the clayey marly deſcriptions, to thoſe of the light ſandy ſorts, are capable of affording it; but that it is obviouſly the moſt ſuited to ſuch light lands as are remarkable for promoting a quick vegetation and growth in the grain. And it is of great importance to be known, that land of the fenny kind, with a bottom of the turf-earthy ſort, is particularly calculated for the growth of this ſort of wheat, and that it riſes in a more quick and ſpeedy manner on ſuch land than on any other kind. Lands of this quality not being well ſuited to the growth of winter wheat, which is liable to be thrown out of them by froſty ſeaſons, on account of their lightneſs; by having all ſuch lands, in the different parts of the united kingdom, ſown in ſuitable courſes with ſpring wheat, a vaſt ſcarcely calculable advantage, it is thought, would be produced.

It is alſo a matter of very great moment, it is ſaid, that ſpring wheat is capable of being grown in different diſtricts where winter wheat cannot be raiſed at all, nor any other ſort of crop of nearly the ſame value or importance; as, for inſtance, in the northern parts or Highlands of Scotland, where they grow an inferior ſort of barley, commonly called *bear* or *bigg*, which is now become of little value, in conſequence of the preſſure of taxation; as, from the quickneſs of its growth, it would be the moſt likely to anſwer and ſucceed in ſuch ſituations. Were only one half of the ground now employed in the growth of bear or bigg crops, it is ſaid, appropriated to the raiſing of ſpring wheat; it would furniſh a quantity of this ſort of grain, equal to the uſual average of imported wheat, and any foreign ſupply be unneceſſary. The propriety of growing ſpring wheat in theſe ſituations, and the iſlands connected with them, is ſtill more ſtrongly enforced, it is ſaid, by the high opinion which has been formed of it by the late Dr. John Walker, profeſſor of natural hiſtory in the univerſity of Edinburgh, in a work lately publiſhed, entitled the "Economical Hiſtory of the Hebrides and Highlands of Scotland," which is equally deſerving the attention of the ſouthern, as well as the northern cultivator, though more particularly calculated for the latter. After noticing the time and manner in which it was brought into that country, as already ſeen, and the nature of its growth and produce in different ſorts of land, it is remarked, that it "will be allowed, that our common winter wheat could not have afforded ſuch a crop, or indeed any crop in the ſame ſpace of time. It appears, therefore, to be a grain better adapted for a northern than a ſouthern climate; that it might be raiſed in many parts of the ſouth of Scotland, where winter wheat is not ſown; and that of all the different ſorts of wheat, *it* is the moſt *promiſing* to be attempted in the Highlands."

In reſpect to the means of procuring or providing the ſeed of this ſort of wheat, it has been ſtated by ſir Joſeph Banks, in a paper inſerted in the fifth volume of Communications to the Board of Agriculture, that as in the neighbourhood of the towns of Boſton and Spalding in Lincolnſhire, the growth and cultivation of it are now fully eſtabliſhed, and likely to continue; from either of theſe places, conſequently, the ſeed may at any time be procured without difficulty, in ſuch quantities as are wanted, even when conſiderable; and that, as there is a water communication between theſe two places, and as the former is a ſea-port, it may always be brought to the metropolis, or any other maritime part of the country, at a ſmall charge. It may conſtantly be had at the above ſea-port at the ſame or ſomewhat leſs prices than winter wheat. And any of the principal merchants at it may be depended on for a proper ſupply. In ſmall portions, many of the chief ſeedſmen in the metropolis or any large towns can moſtly ſupply it.

It would appear on the whole, from the account which has been given of the hiſtory, nature, properties, uſes, and advantages, as well as other circumſtances in reſpect to ſpring wheat, that a more full and general introduction of it into the ſyſtems and practices of arable farming, eſpecially on light and ſome other lands, where the regular wheat huſbandry cannot be carried on, muſt be of very conſiderable importance, not only to the intereſts of individuals, but to the nation at large, in affording better and more certain profits, and at the ſame time guarding againſt the danger of ſcarcity.

Spring *Bay*, in *Geography*, a bay on the N.E. coaſt of the iſland of Barbadoes.

Spring *Iſland*, a ſmall iſland near the coaſt of South Carolina. N. lat. 32° 22′. W. long. 80° 57′.

Spring *Townſhip*, a townſhip of Pennſylvania, in Centre county, containing 1550 inhabitants.

SPRINGE, or Hallerspringe, a town of Weſtphalia, in the principality of Calenberg, the chief trade of which conſiſts in beer; 12 miles E. of Hameln.

SPRINGER, in *Ichthyology*, a name given by authors to the grampus.

SPRINGERS, in *Architecture*, the ribs of a groin, or concentrated arch, which ſpring from their reſpective impoſts, and meet together in an orb or knot in the centre of the whole vault. The ribs of the arches were uſually made of hard ſtone, while light toph ſtone or chalk was preferred for filling up the interſtices.

SPRINGES, a ſort of horſe-hair nooſes, made ſo as to run very eaſy, and planted in the places where birds run in ſome particular path, to take them as they paſs.

Thoſe birds that frequent the waters, or love to paddle and feed in wet and plaſhy places, are the moſt eaſily taken by ſnares.

The ſportſmen who would uſe them to advantage, muſt firſt carefully ſearch out the haunts and places where the fowls come in flocks, or in couples, and feed in the morning and evening hours. The furrows and water-tracks in theſe places are principally to be regarded; and wherever the ſeveral furrows, or water-courſes, meet in one, and afterwards divide into ſeveral others, theſe places are to be remarked above the reſt: the places which have moſt marks of the birds' feet, give alſo the ſureſt of all proofs, that they are well frequented. When theſe places are found, there ſhould be placed a number of ſmall and ſhort ſticks croſſwiſe athwart all the other paſſages, one ſtick being placed about half an inch from another, and making together a kind of fence, guarding every way, except that one through which it is intended the fowls ſhould paſs. This being done, a good ſtiff ſtick is to be provided, cut flat on each ſide; both ends of this ſtick are to be planted under water, ſo that the upper part of the flat ſide may only be upon a level with the ſurface; then a bow is to be made of hazel, or willow, in the form of a pear, broad and round at one end, and narrow at the other, and at leaſt a foot long, and five or ſix inches wide: at the narrow end of this there is to be a nick or dent. Then a ſtiff young grown plant of hazel, elm, or withy, is to be choſen, being buſhy and clear, and without knots, three or four inches about at the bottom, and about an inch at the top. Having made the bottom end of this ſharp, at the top of it there muſt be faſtened a very ſtrong loop, made of about a hundred horſe-hairs, platted very faſt together with ſtrong packthread, and made to ſlip any way with great eaſe. This nooſe or loop ſhould be juſt of the dimenſions of the pear-faſhioned hoop before-mentioned. Then hard by this loop, and within an inch of the end of the plant, there is to be faſtened, with ſtrong horſe-hair, a broad and thin trigger, made ſharp at both ends. Then the bigger ſharp end of the plant being made faſt in the ground, juſt by the edge of the water, the ſmaller end, with the loop and the trigger, muſt be brought down juſt to the firſt bridge; and the pear-faſhioned hoop being ſet upon the bridge, one end of the trigger muſt be ſet upon the nick in the hoop, and the other end on the nick made on the ſmall end of the plate, which by the violence and bend of the plant will make them all ſtick together till the hoop be removed. This done, the loop is to be laid upon the hoop in ſuch faſhion as the hoop is proportioned; then from each ſide of the hoop little ſticks are to be pricked, as before directed, making as it were a kind of impaled path-way, widening it all the way as it goes farther from the hoop, and making it ſo conſiderably wide at the end, that any fowl that chances to come that way may be entered a conſiderable way in before ſhe perceives the fence; by this means the bird will be enticed to go ſtraight on to the ſpringe, and as ſoon as ſhe touches it, either with head or feet, ſhe will be certainly caught; and thus, if the plant be ſtrong enough, the largeſt bird may be caught as eaſily as the leaſt.

When the ſmaller fowls, that frequent watery places, are to be taken by this engine, it is to be made only a great deal ſlighter. When it is intended for ſnipes, woodcocks, or the like, the main plant may be of willow, hazel, or grown oſier, or any other pliant wood that will eaſily bend, and will recover its ſtraightneſs again. The uſe of this engine is limited to the winter ſeaſon, and to times when there is much wet upon the ground. If there happen any great froſts, ſo that there is no advantage to be made of the wet places firſt deſcribed, then the ſportſman is to look for ſome place where there is a conſiderable fall, and where the current is not frozen, and in this place the ſpringes are to be ſet; and the greater the froſts are in this caſe, the more birds will be taken.

There is another uſe of ſpringes for birds, which is the taking, by means of them, certain birds on the boughs of trees and in hedges, which is often attended with very great ſucceſs. The ſportſman, for this purpoſe, muſt firſt mark ſome tree where the birds very much reſort; then fix on ſome particular branch that is tolerably ſtraight, and cutting off all the twigs to within a foot or two of the top, he is there to bore a hole through the branch with a piercer or wimble, large enough to admit a gooſe-quill. Then another branch is to be pitched upon, at about a foot diſtance from the firſt, and all its boughs are to pared away up to a certain height. There is to be fixed to this branch a packthread of half a foot long, and at the end of this is to be tied a nooſe of plaited horſe-hair. The branch to which the packthread is faſtened is then to be ſtooped ſo far, that the nooſe may be brought through the hole in the other branch, and faſtened there by means of a little ſtick four fingers long, and hooked at the end juſt fitting the hole, and ſo brought into it, as juſt to ſtop the flying back of the other branch. Then there is to be placed beyond the nooſe ſome bait of a fruit, or inſect, as a cherry, a pear, or a worm, or any other thing of which the bird, intended to be taken, is known to be fond; this is to be ſet in ſuch a manner, that the bird can no way get at it but by ſetting its feet on the ſmall ſtick which ſupports the nooſe and ſtops the hole. The weight of the bird will throw down the ſtick, and the bird will then be caught by the legs, and tied faſt to the branch where the hole is, by the flying back of the other branch where the packthread is faſtened.

There is yet another method in uſe for the taking many kinds of birds, from the partridge or pheaſant to the black-bird. This is made in the following manner, and is to be placed either on the ground, or on a tree, buſh, or hedge, according to the nature of the bird intended to be taken by it. A ſtraight and even piece of willow, or ſallow, is to be choſen, of about ſix feet long, and of the thickneſs of a walking cane; this is to be ſharpened at one end, and ſtuck down into the ground, and at the other end there is to be faſtened a ſmall crook; then two holes are to be made in the ſtick, the one big enough to admit a gooſe-quill, the other ſmaller: and a piece of ſtick is to be choſen, which being bent, will ſpring back to its ſtraightneſs again, ſuch as holly, or the like: this ſhould be about three feet long, and the larger end of it is to be fixed in the larger hole of the firſt ſtick; the ſmaller end muſt have faſtened to it a packthread, at the end of which there is a nooſe of horſehair: this is to be brought through the ſmaller hole, and be pegged in ſo ſlightly, as juſt to prevent its flying back of itſelf. Then the ſpringe or nooſe is to be ſpread on the peg, and a bait, proper for the bird to be taken, is to be placed at a proper diſtance; ſo that the bird cannot come at it but by treading on the peg, which will give way under its weight, and the ſtick, to which the packthread is faſtened, will fly back, and the bird will be conſequently caught in the nooſe, and have its legs drawn cloſe to the other ſtick.

SPRINGFIELD, the *Aaggavan* of the Indians, in *Geography*, a poſt-town of America, in the ſtate of Maſſachuſetts, and county of Hampſhire, on the E. ſide of Connecticut river; 97 miles W.S.W. of Boſton. This townſhip was incorporated in 1645, and contains 2767 inhabitants, a congregational church, a court-houſe, and a number of dwelling-houſes, many of which are ſpacious and elegant. The town lies chiefly on one ſpacious ſtreet, running parallel with the river. A ſtream from the hills, at the eaſtward of this town, falls into this ſtreet and forms two branches, which run in oppoſite directions, one northerly and the other ſoutherly, along the eaſtern ſide of the ſtreet, ſupplying the inhabitants with a ſupply of water for domeſtic uſes. This place has a conſiderable inland trade, with a paper-mill, arſenal and armoury.—Alſo, a town of New Hampſhire, in the county of Cheſhire, containing 814 inhabitants.—Alſo, a town of Vermont, in the county of Windſor, on the W. ſide of Connecticut river, oppoſite to Charleſtown in New Hampſhire, containing 2556 inhabitants.—Alſo, a poſt-townſhip of New York, at the northern extremity of Otſego county; 58 miles W. of Albany; its area being equal to about ſix miles ſquare. Its ſurface is undulated with hills and vallies, and well divided into arable, meadow, and grazing lands. The ſoil in the vallies is principally a deep rich mould. It has ſeveral mill-ſtreams; three houſes for worſhip, one for Preſbyterians, one for Congregationaliſts, and one for Baptiſts; and twelve or thirteen ſchool-houſes. In 1810 it contained 1846 inhabitants, principally compoſed of Engliſh, Iriſh, Dutch, and Scots emigrants. It derives its name from a large, deep ſpring.—Alſo, a town of New Jerſey, in the county of Eſſex, on Rahway river, which furniſhes fine mill-ſeats; 8 or 10 miles N.W. of Elizabeth town; containing 2360 inhabitants, of whom 45 are ſlaves.—Alſo, a poſt-town of New Jerſey, in Burlington county, having good ſoil, and famous for its cheeſe. The inhabitants, who are principally Quakers, having three meeting-houſes, amount to 1500. The buſineſs is chiefly tranſacted at a village called Job's Town, 10 miles from Burlington. In this townſhip is a hill, called mount Piſgah, which furniſhes ſtone for building. This townſhip has a grammar-ſchool.—Alſo, a townſhip of Pennſylvania, in Montgomery county, containing 550 inhabitants.—Alſo, a townſhip of Pennſylvania, in Bucks county, containing 1287 inhabitants.—Alſo, a townſhip of Pennſylvania, in Delaware county, containing 541 inhabitants.—Alſo, a townſhip of Pennſylvania, in Huntingdon county, containing 751 inhabitants.—Alſo, a townſhip of Pennſylvania, in Mercer county, containing 330 inhabitants.—Alſo, a townſhip of Ohio, in the county of Champaign, containing 598 inhabitants.—Alſo, a poſt-town in Hampſhire county, Virginia, 140 miles from Waſhington.—Alſo, a poſt-town in Waſhington county, Kentucky, 629 miles from Waſhington.—Alſo, a townſhip of Ohio, in the county of Columbiana, containing 601 inhabitants.—Alſo, a townſhip of Ohio, in the county of Hamilton, containing 2063 inhabitants.—Alſo, a townſhip of Ohio, in Jefferſon county, containing 746 inhabitants.—Alſo, a townſhip of Ohio, in the county of Muſkingum, containing 919 inhabitants.—Alſo, a townſhip of Ohio, in Portage county, containing 510 inhabitants.—Alſo, a townſhip of Ohio, in Roſs county, containing 972 inhabitants.—Alſo, a town

town of Kentucky, in Waſhington county, containing 249 inhabitants.—Alſo, a poſt-town in Robertſon county, Teneſſee, 763 miles from Waſhington.

SPRINGHILL, a townſhip of Pennſylvania, in Fayette county, containing 1837 inhabitants, of whom nine are ſlaves.—Alſo, a townſhip of the Indiana territory, in the county of Clark, containing 1107 free inhabitants and ſeven ſlaves.

SPRINGVILLE, a townſhip of the Indiana territory, in the county of Clark, containing 1380 free inhabitants and 13 ſlaves.

SPRINGY or ELASTIC *Body*. See ELASTIC *Body*.

SPRINGY *Land*, in *Agriculture*, ſuch as is ſubject to the breaking forth of ſmall oozing ſprings. It is a ſort of ground very troubleſome to the farmer in the cultivation, as requiring much draining, and other management, to render it proper for cropping. See DRAINING *of Land*; and SOIL. See alſo SPRING-*Draining*.

SPRINTZNSTAIN, in *Geography*, a town of Auſtria; 7 miles S. of Aigen.

SPRIT, in *Agriculture*, a term ſometimes made uſe of to ſignify a young ſprout or ſhoot, as in the caſe of new-ſown grain of any kind. Thus, new-ſown corn is often ſaid to be juſt ſprit, by the farmer. It alſo denotes, in ſome caſes, ſprouted corn; as that which is grown or ſprit in the ſheaf or ſtraw, in the field, from moiſt weather.

SPRIT, in *Sea Language*, is a ſmall boom, or pole, which croſſes the ſail of a boat diagonally, from the maſt to the upper hindmoſt corner of the ſail, which it is uſed to extend and elevate; the lower end of the ſprit reſts in a ſort of wreath or collar, called the *ſnotter*, which encircles the maſt in that place: ſails of this kind are accordingly called ſpritſails. See SAIL.

SPRITSAIL, a ſquare ſail uſed under the bowſprit.

SPRITSAIL-*Topſail*, a ſquare ſail uſed under the jib-boom, but is no longer to be ſupplied in the navy.

SPRITTING, in *Agriculture*, a term applied to the act or proceſs of germinating, ſprouting, or ſhooting forth, either in the work of vegetation, or the operation of malting barley, or other kinds of grain. It is of much conſequence, in both theſe caſes, that the proceſs takes place in a proper manner; as, without it, neither good and perfect field ſeed-crops nor malt can be produced. In moiſt or wet harveſt ſeaſons, the ſpritting of the grain, or other matters, in the ſheaf or ſtouk, in the field, is often of much injury, inconvenience, and loſs to the farmer, and ſhould always be guarded againſt as much as poſſible, by proper ſtouking, hutting, mowing, or ſome other means in ſuch a ſituation. See HARVESTING *Grain*.

SPROD, among the fiſhermen of many parts of England, a name given to the ſalmon while in his ſecond year's growth.

SPROE, in *Geography*, a ſmall iſland of Denmark, ſituated in the Great Belt. Veſſels which paſs the Great Belt in winter are often obliged to ſhelter here, though there is only one farm on the iſland. During winter the poſt regularly ſtops here; and an ice-boat, conducted by five men, is provided for the convenience of paſſengers, letters, &c.; 8 miles N.W. of Corſoer. N. lat. 55° 22′. E. long. 10° 59′.

SPROTTAU, a town of Sileſia, in the principality of Glogau, on a river of the ſame name, at its conflux with the Bober; 21 miles W.S.W. of Glogau. N. lat. 51° 32′. E. long. 15° 32′.—Alſo, a river of Sileſia, which runs into the Bober, at the town of Sprottau.

SPROUT, in *Agriculture* and *Gardening*, the common name of the young ſhoot, offſet, or ſucker, which is thrown or ſent off from any part of a vegetable of the plant, tree, or ſhrub kind.

Fruit-trees and ſhrubs, which are deſigned for production, muſt conſtantly be kept pretty free from theſe ſorts of ſprouts, ſhoots, and ſuckers, or their capability of affording good fruit will be much leſſened and reſtricted. This is particularly the caſe in the gooſeberry and currant ſhrubs, which ſcarcely produce any at all, where they are let remain. See OFFSET and SUCKER.

In hedge plants, however, the ſending off numerous ſprouts or ſhoots from the inferior and bottom parts of their roots and ſtems, is often of very conſiderable utility, in rendering the lower portions of the fences more thick and cloſe, where it does not too much injure the growth and ſtrength of the plants which are made uſe of for the purpoſe, as is ſometimes the caſe. See HEDGE and QUICKSET *Hedge*.

In the practice of gardening, ſprouts or ſhoots are occaſionally, though not frequently, employed for raiſing new crops of vegetables of the ſame kind as the original plants. This is ſometimes the caſe in the cabbage, and a few other ſimilar kinds, as well as in ſome ſorts of tree and ſhrubby plants.

But though the ſlips of the ſprouts or ſhoots, in the cabbage tribe of plants, will readily take root and grow, when planted out while they are in a young ſtate, they are only proper to be made uſe of in this way in an occaſional manner, in particular caſes and circumſtances; as, for inſtance, in planting them for ſeed in any particularly good and valuable ſort. In which caſe, ſome of the beſt ſlips of the ſprouts, in the more early crops, may be taken off, on the approach of the autumnal ſeaſon, and be planted out in rows, at the diſtance of about two feet from each other, giving them frequent waterings at firſt, when they will take root and grow ſo as to eſtabliſh themſelves in a ready manner, ſhooting up to form ſeed-ſtems in the enſuing ſpring, from which ſeed of the moſt perfect kind may be collected and ſecured.

The ſprouts, ſuckers, and ſhoots, of plants of the tree or ſhrub kinds are, in ſome caſes, ſlipped off and uſed in raiſing young trees and ſhrubs of the ſame ſorts as the originals, with the greateſt certainty, and in the moſt eaſy and expeditious manner. In ſuch intentions, the ſlips or ſhoots are, for the moſt part, taken off in the early ſpring, or towards the autumn, and planted out in rows in the nurſery grounds, at ſuitable diſtances, according to their nature and habits of growth; or placed in pots, to be ſet out in the open ground, or to be forced forward by the heat of the hot-beds, in the ſtoves, hot-houſes, frames, and other ſimilar compartments of the garden. They are afterwards, as ſoon as they have ſtricken or taken full root, in many caſes, removed and put out in different ways, according to circumſtances, and their particular nature and habits, as is ſhewn in ſpeaking of the culture of the different ſorts, under their proper heads.

SPROUTS, *Eſculent*, the fine, ſmall, young, tender, green ſhoots, which are ſent off and produced from the ſides or other parts of different kinds of culinary vegetables or plants, and made uſe of as human food at different periods and ſeaſons of the year. There is a great number of garden vegetables which afford ſprouts of this nature, and ſome in conſiderable abundance as crops for this purpoſe; as thoſe of the *braſſica* tribe in particular, as ſeen below.

In ſome herbaceous eſculent plants the young ſprouts are excellent eating, as in the cabbage kinds, and ſome others, affording a very profitable after-crop. The ſprouts produced on the ſtalks of the early-cut cabbages often alſo cabbage into tolerable little firm heads towards autumn, in the ſugar-loaf cabbage particularly, and other forward kinds; producing abundance of fine ſprouts in ſummer, which, being gathered while young and green, conſtitute ſome of the moſt excellent culinary greens of the ſeaſon. Likewiſe forward ſavoys, being cut early in autumn, the remaining ſtalks produce fine large ſprouts the ſame year, fit for uſe in the early part of winter: later crops of the ſame plants produce alſo abundance of ſmall ſprouts in the ſpring; and the borecole is remarkable for its great production of ſprouts towards ſpring, emitted all along the ſmall ſtems from the very bottom to the top: alſo, purple brocoli never fails to produce a ſecondary crop of excellent ſprouts, furniſhed with little tender heads.

In the culture of all the varieties of the cabbage kind, it is proper, therefore, after gathering the main heads, to leave a quantity of the ſtalks of the beſt and more forward crops, of the reſpective ſorts, to produce ſprouts; and if, towards autumn or winter, and other ſeaſons, the ground ſhould be wanted for other crops, the ſtalks may be removed, and trenched in by the roots in another place, not in a ſhady bye corner, as often practiſed, nor placed too cloſe, as the ſprouts would, in ſuch caſes, prove ſmall and trifling, and be liable to be eaten up by ſlugs; but in an open ſituation, in rows a foot aſunder: in which method the ſprouts will continue their growth in much greater perfection, though probably not in ſo good condition as if the ſtalks had remained undiſturbed.

As the ſtalks of cauliflowers and cauliflower-brocoli rarely produce any ſprouts, it is needleſs to leave them ſtanding on the ground, after their heads have been cut from them.

The ſprouts of this kind which are produced in the ſummer and autumnal ſeaſons are by much the fineſt, and continue the longeſt in perfection; yet, though the ſpring ſprouts may be of a ſmaller ſize, and continue a much ſhorter time before they run up for producing ſeed, they are, notwithſtanding, often found highly advantageous, uſeful, and acceptable at ſuch a ſeaſon, on account of the great deficiency of other ſorts of green vegetable products, and for the variety which they afford at the table.

All ſprouts of this nature, and for this uſe, ſhould conſtantly be plucked or taken off from the ſtems of the old plants while they are in their young, full, and early growth, in order that they may boil in a green and tender manner; as they are liable to become hard and ſticky, when left to an old ſtate of growth, and are not by any means ſo ſaleable in the market.

SPROUTS or *Shoots of Potatoes, Planting of.* Theſe are the ſprouts, ſhoots, or running branches, which are ſent off from them in their early growth. Such young ſprouts or ſhoots have lately had different experiments made with them, by which it has been ſhewn, that they are capable of being uſed with advantage in raiſing crops of this very neceſſary root, in ſome caſes. In Suſſex, the earl of Egremont, according to the writer of the corrected account of the agriculture of that diſtrict, has taken much intereſt in trials for raiſing them in this way.

In regard to the method of breaking off the ſprouts or ſhoots from the potatoes, there is no reaſon, it is ſaid, to be apprehenſive how or in what manner they are taken off; and if the ſprouts or ſhoots, after they have been ſeparated from the potatoe, be put into a baſket, and have a little earth thrown over them, they will keep in this ſtate, it is aſſerted, if not immediately wanted, for months. The kidney potatoe, after its ſecond cropping, is noticed to decreaſe in the number of its ſprouts or ſhoots. No ſort is ſuppoſed to equal the red cluſter kind. The early kidney comes up before any other ſort; the cluſter is the next; and the ox-noble the laſt. The cluſter throws out more ſprouts or ſhoots than any other kind, even ſo far as up to thirty at a time.

The ſprouts or ſhoots are planted promiſcuouſly from one to ſix or ſeven inches in length. Until the third or fourth month after planting, the ſprouts or ſhoots have, it is ſaid, but a ſmall apple, not above the ſize of the end of a perſon's finger; but afterwards they wonderfully increaſe their ſize. Hence it follows, it is ſuppoſed, that the eye, having a greater and more ſubſtantial root to ſupport the vegetative power of the plant, comes eaſier to perfection; but that the ſprout or ſhoot, though ſtationary at firſt, will in the end more than equal the other in produce; and if to this be added the ſaving of ſeed, the advantage will be ſtill more conſiderable.

Hence it is ſaid, that it may be inferred, that this method of cultivating the potatoe, which is practiſed at Petworth, in the above county, with ſucceſs, merits the attention of farmers, and probably of garden cultivators alſo. For an early market it is the only method, it is thought, of raiſing them; and beſides, the ſeed and expences of cutting are ſaved.

It has been long known that the potatoe is capable of being readily raiſed by planting the ſprouts or ſhoots, and recourſe has, for a conſiderable length of time, been had to it, in ſome meaſure, for the production of early crops, in the county of Lancaſter.

The want of ſubſtance in the ſprouts or ſhoots would ſeem to be a great objection to the ſprout manner of raiſing potatoe crops, as there muſt be a deficiency of ſupport in the early growth of the plants which conſtitute ſuch crops; as it has been found that even ſmall cuttings, where the eyes are preſerved, are not ſo good for raiſing full crops, on account of their want of ſubſtance, as thoſe of large ones; and ſcooped eyes, as ſets, have now almoſt been wholly rejected by cultivators, in conſequence of their defect of ſubſtantial nutrient matter for the ſupport of the young plant in its firſt or very infant growth. The matter remains, however, to be fully cleared up, and placed in a decided point of view, by more full and more correct trials made directly in this intention, as the ſprouts or ſhoots are unqueſtionably the natural modes in which the plants are raiſed. See POTATOE and SOLANUM.

SPROUT-*Hill*, a name ſometimes given to the ant-hill. See ANT-*Hill*.

The moſt ready way of removing ſprout-hills is probably by frequent heavy rolling of the land, immediately on their firſt appearance. The turning of a ſtream of water over the ground, where it can be conveniently done, may alſo ſometimes perhaps be effectual in the ſame intention. There are different implements and machines which perform this ſort of work in a very complete, expeditious, and effectual manner, that may be had recourſe to for the purpoſe. See SWARD-*Cutter*, and STRIKING *Ant-hill Machine*.

SPROUTING, the germination or firſt ſending forth of youg ſprouts from ſeeds, cuttings, or plants.

The ſprouting and early growth of almoſt all ſorts of field and garden ſeeds and plants are greatly promoted by placing them to proper depths, in properly dry and ſuitably rich ſoils and ſituations, as well as by a nice attention to their culture, while they are in their young riſing ſtate or condition. This is particularly the caſe in the latter ſorts of ſeeds and plants.

SPRUCE, *Eſſence of*, a fluid extract, prepared by coction of the twigs of the wild pine or Scotch fir. See Pinus *Sylveſtris.*

Spruce-*Beer*, a beverage made of the eſſence of ſpruce, fermented with ſugar or moloſſes and water.

Spruce, in *Geography*, a ſmall American lake of New Hampſhire, near Cheſterfield.

Spruce *Creek*, an American creek, which winds its courſe through the marſhes from the mouth of Piſcataqua river five or ſix miles to Kittery, in York county, Maine.

SPRUNT, in *Rural Economy*, a term ſignifying a ſteep road, or one on which there is much difficulty in paſſing with teams, and which requires great exertion in them.

SPRY, in *Agriculture*, a name ſometimes applied to the flat broom which is uſed with the caſting ſhovel, in the operation of cleaning grain, for ſweeping off the chaffy materials that collect in the work.

Spry *Harbour*, in *Geography*, a bay on the ſouth-eaſt coaſt of Nova Scotia. N. lat. 44° 42′. W. long. 62° 40′.

SPUD, in *Agriculture*, a tool or implement of the fork ſort, with three broad prongs of conſiderable ſtrength, which is uſeful for ſeveral different purpoſes. See Hop.

SPUDING, the practice or operation of digging over the hop-grounds, by means of the ſpud, in different diſtricts. This ſort of work ſhould always be fully, carefully, and expeditiouſly performed, as a great deal of the ſucceſs of the crops depends upon theſe circumſtances. See Hop.

SPULLERS *of Yarn*, in our *Old Writers*, perſons that work at the *ſpole*, or *wheel*. It alſo denotes triers of yarn, to ſee if it be well ſpun, and fit for the loom.

SPUN-Hay, in the *Military Art*, hay twiſted in ropes, very hard, for an expedition in the winter time; each trooper carrying as much as he can behind him.

SPUNGE, or Sponge, *Spongia*, in *Natural Hiſtory*, a kind of marine ſubſtance, found adhering to rocks, ſhells, &c. under cover of the ſea-water, or on the ſides of the rocks about the ſhore. See Spongia.

The ancients diſtinguiſhed two kinds, *male* and *female:* but the moderns make only one kind; which, however, they diſtinguiſh, with regard to its texture, into *coarſe* and *fine.*

Naturaliſts have been embarraſſed in all ages, whether to range ſpunge in the animal, mineral, or vegetable family. Some would have it a concretion formed of the ſea-mud; others have commonly ſuppoſed it to be a vegetable production: but it is now allowed to be, like the corallines, of animal origin; being the fabric and habitation of ſome ſpecies of worm or polype.

Dr. Peyſſonel has actually diſcovered and deſcribed the worms that form four different ſpecies of ſpunges, without having it in their power to dilate and contract them, as ſome naturaliſts have ſuppoſed; the ſpunges being altogether inanimate bodies, and inſenſible to the touch, or to any motion of the ſea, or any other accident, and formed by the juice or ſlaver which is depoſited by the worms that inhabit them. Phil. Tranſ. vol. l. art. 78. p. 590, &c.

Mr. Ellis, to whoſe obſervations on productions of this kind the public are much indebted, informs us, that if we carefully examine a ſmall part of one of thoſe ſpunges, whoſe ramifications are large and diſtinct, in the microſcope, we ſhall find that they riſe from many ſmall tubes: theſe, as they extend themſelves upwards, ſend outſide branches in various directions, which inoſculate, and, uniting thus with each other, form a compound reticulation quite through the inſide of the whole maſs. In viewing the extremities of the upper or laſt ſhoots, we may perceive ſmall openings at the end of their fibres; and as we trace theſe fibres back from the opening downwards, we ſee a ſoft whitiſh ſubſtance, which fills the internal hollow part of all the ramifications through the whole ſpunge; which ramifications have much the appearance of tranſparent catgut of an amber colour, and are, without doubt, the lodgments of animals of a particular claſs. For though we cannot diſtinguiſh either veſicles, or cells, or diſcover any other kind of organization, than that of a hollow tube variouſly inflected, and wrought together into a multitude of agreeable forms, ſome branched like corals, ſome expanded like a fungus, ſome riſing up ſtraight like a column; others broad at top, with a narrow baſe, and hollow like a funnel, with regular cavities, entrances, or apertures, which are nearly alike in all ſpunges of the ſame ſpecies; yet, from many obvious reſemblances to divers other claſſes of ſea productions, which are found to be of animal conſtruction, and from the chemical analyſes of ſpunges in general, there ſeems ſufficient reaſon for referring them to the claſs of animal productions. Ellis's Nat. Hiſt. of Corallines, &c. p. 78.

Spunge, or *Sponge*, in *Chemiſtry* and the *Materia Medica*, is the *ſpongia officinalis*, for an account of which, ſee Spongia. This ſpecies of ſpunge is found chiefly in the Mediterranean and Red ſeas.

On ſome of the iſlands of the Archipelago, the inhabitants are trained from their infancy to dive for ſpunges, which are generally found attached to the bottom of the rocks. This ſubſtance, formerly ſuppoſed to be of a vegetable nature, but determined by the obſervations of Mr. Ellis (ſee Phil. Tranſ. vol. lv.) to be of animal origin, has been, not long ago, examined by Mr. Hatchett, in the courſe of his valuable experiments on the component parts of animal membrane. (See Phil. Tranſ. vol. xc. p. 352, &c.) The ſpunges particularly examined by this ingenious chemiſt, are the S. cancellata, S. oculata, S. infundibuliformis, S. palmata, and S. officinalis. When the ſpunges had been immerſed in nitric acid (diluted with three meaſures of diſtilled water) during fourteen or ſixteen days, the acid became pale yellow, and was changed to an orange colour, by the addition of pure ammonia. After this proceſs the ſpunges became more or leſs tranſparent, and were conſiderably ſoftened. In this ſtate, if they were touched with ammonia, the part thus touched aſſumed a deep orange colour, inclining to a browniſh-red; and when much ſoftened by the acid, (if afterwards immerſed in ammonia,) they were completely diſſolved, and formed a deep orange-coloured ſolution. When digeſted with boiling diſtilled water, the ſpunges afforded a portion of animal jelly or gelatin (ſee Gelatin), which was precipitated by infuſion of oak-bark. In conſequence of their loſs of gelatin, which was imparted to the water, the ſpunges became leſs flexible, and more rigid; and the remaining part, when dry, crumbled between the fingers; or, when moiſt, was torn eaſily, like wetted paper. From theſe properties it appears, that ſpunges only differ from the horny ſtems of the gorgoniæ, and from the antipathes, by being of a finer and more cloſely woven texture; and this is particularly obſervable by comparing the coarſe ſpunges (ſuch as S. cancellata) with the finely reticulated parts of certain gorgoniæ, eſpecially the gorgonia flabellum, when diveſted of the external membrane. When the ſpunge, either in its natural ſtate, or eſpecially when its gelatin has been extracted by long boiling with water, is boiled with lixivium of cauſtic potaſh, it is completely diſſolved in it, and forms an animal ſoap. Spunge, when heated in a cloſe veſſel, gives out an ammoniacal fetid ſmoke, and is reduced to a black charcoal, which, after incineration, leaves a ſmall quantity of common ſalt and ſome carbonate of lime. The principal conſtituents of ſpunge, according to Mr. Hatchett's experiments, are animal gelatin, albumen (which ſee), a ſmall portion of common ſalt, and carbonate of lime. Spunge, when cleaned and fit for uſe, is of a browniſh-yellow colour, ſoft, light, and very porous; abſorbing rapidly by capillary attraction as much as it can contain of any fluid in which it is immerſed, and again yielding it when compreſſed.

Spunge is a very uſeful ſubſtance in the arts. In its uſual form it is never employed as a remedy; but in ſurgery, it is a very uſeful inſtrument on various occaſions.

A ſpunge applied to bleeding veſſels has been found a very ſucceſsful method of ſtopping the effuſion of blood. Phil. Tranſ. N° 478. p. 33.

For this purpoſe, a very dry and ſolid piece, of a cubical or conical form, ſhould be applied in cloſe contact with the veſſel, and retained by proper compreſſion; and it will ſoon adhere with great force. Very large arteries have been prevented from bleeding by this application.

Dry ſpunge, from its property of imbibing and ſwelling by moiſture, is ſometimes uſed as a tent for dilating wounds and ulcers: for this purpoſe, after being carefully freed from the ſmall ſtones generally lodged in it, it is dipt in melted wax, and the wax ſqueezed out from it in a preſs. Lewis.

Taken inwardly, it choaks; and is, for that reaſon, cut ſmall, and fried or dipped in honey, and given to quadrupeds to kill them, which it ſeldom fails to do, by ſwelling and preventing the paſſage of the food into the inteſtines.

The officinal preparation of ſpunge for medical purpoſes is the "ſpungia uſta," or burnt ſpunge. The London Pharmacopeia directs to cut ſpunge into ſmall pieces, and to bruiſe it, that it may be thus freed from any adhering extraneous ſubſtance; then to burn it in a covered iron veſſel, until it become black and friable; and, laſtly, to reduce it to a very fine powder. Burnt ſponge conſiſts of carbonate and phoſphate of lime, ſubcarbonate of ſoda, and charcoal. The principal active ingredient is the ſubcarbonate of ſoda; but it is aſſerted, that a mixture of this principle and charcoal does not produce the effects of burnt ſpunge. This ſubſtance is tonic, deobſtruent, and antacid. It has been much recommended in bronchocele, ſcrophulous affections, and hepatic eruptions. The doſe is from ʒj to ʒiij, mixed into the form of an electuary, with powdered cinnamon and honey. In bronchocele the patient is directed to ſwallow the portion of electuary very ſlowly, from a ſuppoſition that ſome local effect is produced. See Bronchocele.

Some have pretended to cure the leproſy with it, and others extol it againſt the bite of a mad dog; but theſe laſt are virtues not univerſally received.

In ſpunges are found a kind of ſtones called *cyſtiolithi*, held good for the worms in young children, and to this purpoſe given in powder.

Spunge, in the *Manege*, is the extremity, or point of a horſe's ſhoe, that anſwers to the heel of his foot; upon it the calkins are to be made. Thick ſpunge ruins the horſe's heels, and therefore ought never to be uſed. See Shoeing *of Horſes.*

Spunges, *Pyrotechnical*, are made of the large muſhrooms or fungous excreſcences growing on old oaks, aſhes, firs, &c. which, being boiled in common water, then dried and well beaten, are put into a ſtrong ley, prepared with ſaltpetre, and again dried in an oven.

Theſe make the black match or tinder brought from Germany, uſed to receive and ſuſtain the fire ſtruck from a flint and ſteel, &c.

Spunge is uſed, in *Gunnery*, for a cylinder of wood, from ten to twelve inches long, of the ſame diameter with the rammer, with a piece of ſheep or lamb-ſkin wound about its end, to ſerve for ſcouring great guns when diſcharged, before they be charged with freſh powder; hence called *ſpunging*. In ſmall guns it is commonly fixed to the other end of the handle of the rammer; but has a ſeparate one in thoſe of a larger calibre.

SPUNGING. See Spunge.

SPUNK, a term uſed indifferently for half-rotten wood, match for guns, and a ſubſtance growing on the ſides of trees. See Agaric.

SPUN-YARN, among *Sailors*, a ſmall line or cord, formed of two or three rope-yarns twiſted together by a winch; the yarns, of which it is uſually made at ſea, are drawn out of the ſtrands of old cables, or other ropes, and are knotted together, and tarred. It is employed for ſeveral purpoſes, particularly to faſten one rope to another, to ſeize block-ſtrops to the ſhrouds, and to ſerve ropes which are liable to be chafed, &c.

SPUR was anciently a piece of the armour of a cavalier, faſtened to the talary, that is, the hind part of that piece of a complete armour which covers the legs and feet.

The word is derived from the German, *ſpohr*; or rather the Saxon, *ſpora*; or Daniſh, *ſpor*; which all ſignify the ſame.

At preſent, the ſpur is a piece of iron, or other metal, conſiſting of two branches encompaſſing the horſeman's heel, and a rouelle or rowel in form of a ſtar, advancing out behind, to prick the horſe.

Louis le Debonnair forbad eccleſiaſtics the profane faſhion of wearing ſpurs. Anciently the difference between the knight and eſquire was, that the knight wore gilt ſpurs, whence the appellation of *eques auratus*; and the ſquire, ſilvered ones.

Two ſorts of ſpurs ſeem to have been in uſe about the time of the Conqueſt, one called a pryck, having only a ſingle point, like the gaffle of a fighting-cock; the other conſiſting of a number of points of conſiderable length, radiating from and revolving upon a centre, thence named the rouelle, or wheel-ſpur. Delineations of the firſt occur in the ſeals of moſt of our kings and great barons, prior to the reign of Edward III., and alſo on the engraved and ſculptured figures of croſs-legged knights. The rouelle is ſometimes found on figures of equal antiquity; inſtances occurring of the ſame perſon being delineated with the pryck-ſpur on one ſeal, and the rouelle on another. Some ſpecimens of the pryck-ſpur are ſtill to be found in the cabinets of the curious.

Spur, *Order of the Golden*, in Rome, is ſuppoſed by ſeveral writers to have been inſtituted by pope Pius IV., in 1559. The badge is a ſtar of eight points argent, and between the two bottom points a ſpur or.

Spur, in *Agriculture*, the name of a vegetable diſeaſe, which frequently attacks rye, and which ſometimes likewiſe damages wheat. It is found that the grains which have the ſpur are thicker and longer than the ſound ones, and generally project beyond their huſks, appearing ſometimes ſtraight, and ſometimes more or leſs crooked; and that their outſides are brown or black; their ſurface is rough, and three furrows may frequently be perceived in them, which run from end to end. Their outward end is always thicker than that which ſticks to the chaff, and the moſt ſwollen end is ſometimes ſplit into two or three parts. It is not unuſual to find on their ſurfaces cavities which ſeem to have been made by inſects. Further, that when a ſpired grain is broken, in the middle or centre of it is ſeen a pretty white flower, covered with another flower, which is reddiſh or brown. Though this vitiated flower has ſome conſiſtency, it may nevertheleſs be crumbled between the fingers. M. Aimen has ſometimes found this powder almoſt as black as that of ſmutty wheat. Theſe grains, when put into water, ſwim at firſt, and afterwards ſink to the bottom. If chewed, they leave a bitter taſte on the tongue. The chaff appears ſound, though what is outmoſt is ſomewhat browner than when the ears are ſound. But all the grains of the ſame ear are not ever attacked with the ſpur. The grains which have this diſtemper ſtick leſs to the ſtalks than ſound grains do. And the above writer imputes the diſtemper to the grains not being impregnated; and aſſerts, that he has not ever found a germ in grains which had the ſpur.

It may be noticed, that it has been ſuppoſed by ſome that fogs, dews, rain, and the moiſture of the earth, may give the diſtemper to rye, but without any ſufficient reaſon. M. Tillet is however ſtrongly inclined to think that it is occaſioned by an inſect, which turns the rye into a kind of *gall;* and he ſuſpects a ſmall caterpillar as being the cauſe of this miſchief, but cannot ſpeak affirmatively on this point. It has been abſurdly ſuppoſed to affect thoſe who conſume the bread made from grain thus diſeaſed with a ſort of dry gangrene in the extreme parts of the body. The nature of this diſeaſe in grain, like thoſe of many others, is ſtill far from being fully inveſtigated, ſo as to form any correct notion of the means of removing or preventing it.

Spurs, in *Old Fortifications*, denote walls that croſs a part of the rampart, and join to the town-wall.

Spurs, in *Ship-Building*, large pieces of timber, the lower ends of which are fixed againſt the ſide of the bildge-ways, and the upper ends fayed and bolted to the ſhip's ſide, to ſupport the ſhip in launching. They have been much diſcontinued of late years.

Spur-*Shell*, a ſpecies of the cochlea.

SPURGE, in *Botany*. See Euphorbia.

Spurge-*Laurel*, or *Mezereon*, *Laureola*, or *Daphne*. See Daphne, and Daphne *Mezereum*.

Spurge, *Olive*, the Engliſh name of a genus of plants, called by ſome botaniſts *chamelæa;* which ſee.

Others have made the olive ſpurge a ſpecies of euphorbia, or ſpurge. See Euphorbia.

Spurge, *Sun*, a name by which ſome call ſeveral ſpecies of *tithymalus;* which ſee.

Spurge-*Root*, in the *Materia Medica*. See Esulæ *Radix*.

SPURGEN, in *Geography*, a town of America, in North Carolina; 22 miles N.N.E. of Saliſbury.

SPURIOUS Diseases, in *Medicine*, are ſuch as, in ſome ſymptoms, cannot be brought under any diſtinct head, and, therefore, are called by the name of others with which they moſt agree. Whence, alſo, they are often denominated *baſtards*, *nothi*.

Such are a ſpurious or baſtard pleuriſy, a ſpurious peripneumony, a baſtard quinſey, and the like. See Pleurisy, Peripneumony, &c.

Spurious *Fleſh*, is an appellation given by ſome to the fleſh of the lips, gums, and that of the glands, &c.

Spurious *Medals*. See Medals.

Spurious *Ribs*. See Ribs.

Spurious *Suture*. See Suture.

SPURKETS, in a *Ship*. See Spirketting.

SPURN Head, in *Geography*, a cape of England, at the S.E. extremity of the county of York, at the mouth of the Humber, on which is a light-houſe. N. lat. 53° 38′. E. long. 0° 18′.

SPURNESS, the ſouth cape of Sunda, one of the Orkney iſlands. N. lat. 59° 7′. W. long. 2° 35′.

SPURNWATER, in *Ship-Building*, a channel left above the ends of a deck, to prevent the water from coming any further.

SPURRE, in *Ornithology*, a name given by many to the bird more commonly called the ſea-ſwallow.

SPURREY, in *Botany*. See Spergula.

Spurrey, *Corn*, in *Agriculture*, the common name of a plant of the weed kind, which is common in many parts and ſituations. It ſeldom riſes above ſix inches in height, flowers in the beginning of July, ripens its ſeed in Auguſt, and is an annual plant. When it is troubleſome as a weed, the beſt method of exterminating it is by ſummer fallows, and cutting it down before it can ſcatter its ſeeds, which are very ſmall.

Two ſpecies of this plant, however, are ſaid to be cultivated in Holland and Flanders, for the winter food for cattle, when there is a ſcarcity of graſs. It is ſaid to enrich the milk of cows, ſo as to make it afford excellent butter; and the mutton fed on it is preferable to that fed on turnips. Hens eat this plant and its ſeeds greedily, and they are ſuppoſed to make them lay a great number of eggs.

It is a plant which is ſown twice a year; the firſt time in April and May, to be ready in June or July; and the ſecond time after the rye-harveſt, to ſerve the cattle in November and December. The uſual allowance of ſeed is about twelve pounds to the acre.

It is ſaid, that though not cultivated in the county of Berks, it grows there in an abundant manner, and that the ſeeds of it might be eaſily collected in any quantity. The cultivation of it has been recommended, by way of trial, on the poor ſoils about Frilſham and Yattendon, in the above diſtrict, by the writer of the account of the agriculture of the county, on the ſuggeſtion of an intelligent perſon. It is ſtated alſo, that Roucel, in his "Flora du Nord de la France," has conſidered it as an excellent late fodder for cows; and that it is made uſe of in the above countries, as well as in Germany, both in its green ſtate, and when made into hay.

It is likewiſe ſuggeſted, that as the knotted ſort of ſpurrey, though perhaps not equally grateful to animals, naturally over-runs the peat-pits in the Kennets, in the above county, it might therefore be ſown with certain effect in ſuch ſituations.

Spurrey, *Purple*, an annual weed in dry ſandy meadows, and corn-fields of the ſame dry quality. There are other ſorts which are troubleſome in wet hedges and woodlands.

SPUR-WAY, in *Rural Economy*, a term applied to a bridle, or horſe-way, or road through incloſed lands or fields, and free to any one to ride in by right of cuſtom or uſage.

SPUR-WING, in *Geography*, a river of America, in the ſtate of Maine, which runs through Scarborough, W. of Cape Elizabeth, and is navigable a few miles for veſſels of 100 tons.

SPUTT, a river of England, in the county of Weſtmoreland, which runs into the Ken.

SPUTUM, in *Medicine*, &c. the ſpittle or excrement voided at the mouth. See Saliva.

An examen of the ſputum is of great conſequence in phthiſical caſes: and Bennet, in his "Theatrum Tabidorum," applies himſelf in a particular manner to it. The *ſputum ſanguinis* is a very dangerous ſymptom in that diſeaſe.

SPY, a perſon paid to watch the actions, motions, &c. of another, particularly as to what paſſes in an army.

The uſe of ſpies is a kind of clandeſtine practice or deceit in war. Spies are generally puniſhed capitally, and immediately when they are diſcovered in a camp; and, ſays Vattel, not unjuſtly, there being ſcarcely any other way to prevent the miſchief they may do. For this reaſon, a man of honour, who would not expoſe himſelf to die by the hand of a common executioner, ever declines ſerving as a ſpy; he counts it beneath him, as it can ſcarcely be done without ſome kind of treachery. The ſovereign, therefore, cannot lawfully require ſuch a ſervice from his ſubjects, unleſs in ſome ſingular caſe, and that of the laſt importance. The mercenaries are allured to it by great rewards. If thoſe whom a ſovereign employs make a voluntary offer, or if they be not the enemy's ſubjects, or have no connection with him, he may unqueſtionably make uſe of their ſervice, without offence to juſtice or honour; but it may be aſked, is it lawful, is it decent, to ſolicit the enemy's ſubjects to act as ſpies, and betray him? Let the following paragraph ſerve as a reply.

If it be aſked in general whether it be lawful to ſeduce the enemy's men, to engage them to tranſgreſs their duty by an infamous treachery? Here we muſt diſtinguiſh between what is due to the enemy, notwithſtanding the ſtate of the war, and what is required by the internal laws of conſcience, and the rules of probity. Now the enemy may be weakened by all poſſible means, provided they do not affect the common ſafety of human ſociety, as poiſon and aſſaſſination. The ſeducing a ſubject to turn ſpy, that of a governor to deliver up his place, does not ſtrike at the foundation of the common ſafety and welfare of ſociety. Subjects acting as the enemy's ſpies, are not a fatal and inevitable evil, they may in ſome meaſure be guarded againſt; and as to the ſecurity of fortreſſes, it is the ſovereign's concern to chooſe proper governors. Thus theſe means are not contrary to the external law of nations, nor can the enemy complain of them as odious proceedings. Accordingly, they are practiſed in all wars. But are they juſt, and compatible with the laws of a pure conſcience? Certainly not. And of this the generals themſelves are ſenſible, as they are never heard to boaſt of having practiſed them. Seducing a ſubject to betray his country, ſuborning a traitor to ſet fire to a magazine, practiſing on the fidelity of a governor, inticing him, perſuading him to deliver up a place, is prompting ſuch perſons to commit deteſtable crimes. Is it honeſt to incite our moſt inveterate enemy to be guilty of a crime? If ſuch practices are at all excuſable, it can be only in a very juſt war, and for ſaving our country, when threatened with ruin by a lawleſs conqueror. The guilt of a ſubject or general who betrays his prince in a cauſe manifeſtly unjuſt, does not appear ſo very odious. He who himſelf tramples upon juſtice and probity, deſerves, in his turn, to feel the effects of perfidy and wickedneſs. And if ever it is excuſable to depart from the ſtrict rules of probity, it is againſt ſuch an enemy, and in ſuch an extremity. Vattel's Law of Nations, b. iii. ch. 10.

Wicquefort ſays, an ambaſſador is an honourable ſpy, under the protection of the law of nations.

SPYCKENS, in *Geography*, a town in the iſland of Voorn; 9 miles E. from the Brill.

SPYRUS, the *dung of goats*. This is uſually found in ſmall round maſſes, and is recommended by Hippocrates as a fumigation in the diſeaſes of the womb.

SQUACCO, in *Ornithology*, the name of a large bird of the heron kind. Its head and neck are variegated with black, white, and yellow, and it has on the back part of its head a creſt of the ſame colour. Its back is of a ferruginous yellow, its breaſt and belly are white, as are alſo its wings and tail, at leaſt in great part, and its legs are green. It is a bold and fierce bird.

SQUAD, in *Military Language*, a diminutive of ſquadron; uſed to denote any ſmall number of men, horſe or foot, that are collected together for the purpoſes of drill, &c. See ESCOUADE.

Hence, to *ſquad* is to divide a troop or company into certain parts, in order to drill the men ſeparately, or in ſmall bodies, or to put them under the direction and care of ſome ſteady corporal, or lance corporal. Each troop ought to be divided into two ſquads, when under 40, and into three, or even four, when above this number, with an equal proportion of non-commiſſioned officers in each: and when the eldeſt is on duty, the charge of the ſquad falls on the next in the ſquad, and ſo on. Recruits ſhould always be quartered and ſquadded with old ſoldiers, who are known to be ſteady and well behaved; and thoſe men that are at all irregular in their conduct, muſt be ſeparated and diſtributed in ſquads which are compoſed of good old ſoldiers.

SQUAD, *Aukward*, conſiſts not only of recruits at drill, but of formed ſoldiers, that are ordered to exerciſe with them, in conſequence of ſome irregularity under arms. The term has likewiſe been uſed, by way of ridicule or reproach, to mark out thoſe officers who are negligent of their duty.

SQUADRON, a body of horſe, whoſe number of men is not fixed, but is uſually from eighty to a hundred and twenty men.

The word is formed from the Italian *ſquadrone*; of the Latin *ſquadro*, uſed by corruption for *quadro*: in regard, at firſt, the ſquadrons were always ſquare, and called alſo by the Latins *agmina quadrata*.

The ſquadron uſually conſiſts of two troops, and each troop of about forty men; a greater number cannot be advantageouſly poſted, nor have room to act in narrow grounds, woods, marſhes, defiles, &c.

The eldeſt troop takes the right of the ſquadron, and the ſecond the left.

SQUADRON *of Ships*, denotes either a detachment of ſhips employed on any particular expedition, or the third part of a naval armament.

The number of ſhips in a ſquadron is not fixed: a ſmall number of veſſels, if they be in a body, and have the ſame commander, may make a ſquadron.

If there be a great number, they are uſually divided into three ſquadrons; and if the ſquadrons be numerous, each ſquadron is divided into three diviſions, diſtinguiſhed by their flags and colours. See DIVISION and FLEET.

SQUAIOTTA, in *Ornithology*, the name of a bird of the heron kind. Its beak is yellow, but blackiſh at the extremity; its legs are green; its head is variegated with grey and black; and its back very elegantly with white and red. It ſeems to have had its name from its note, which it often repeats in flying.

SQUALL, in *Sea Language*, a ſudden and violent blaſt of wind, uſually occaſioned by the interruption and reverberation of the wind from high mountains. Theſe are frequent in the Mediterranean, particularly in the Levant, as produced by the repulſion and new direction which the wind meets with in its paſſage between the various iſlands of the Archipelago. Falconer.

SQUALLEY, a note of faultineſs in the making of cloth. 43 Eliz. cap. 10. Blount. Cowel. See REWEY.

SQUALLY, in *Agriculture*, a term provincially applied to ſuch crops of turnips, corn, rape, &c. as are broken or detached broken, in the middle or centre of it is ſeen a pretty white flower, covered with another flower, which is reddiſh or brown. Though this vitiated flower has ſome conſiſtency, it may nevertheleſs be crumbled between the fingers. M. Aimen has ſometimes found this powder almoſt as black as that of ſmutty wheat. Theſe grains, when put into water, ſwim at firſt, and afterwards ſink to the bottom. If chewed, they leave a bitter taſte on the tongue. The chaff appears ſound, though what is outmoſt is ſomewhat browner than when the ears are ſound. But all the grains of the ſame ear are not ever attacked with the ſpur. The grains which have this diſtemper ſtick leſs to the ſtalks than ſound grains do. And the above writer imputes the diſtemper to the grains not being impregnated; and aſſerts, that he has not ever found a germ in grains which had the ſpur.

It may be noticed, that it has been ſuppoſed by ſome that fogs, dews, rain, and the moiſture of the earth, may give the diſtemper to rye, but without any ſufficient reaſon. M. Tillet is however ſtrongly inclined to think that it is occaſioned by an inſect, which turns the rye into a kind of *gall;* and he ſuſpects a ſmall caterpillar as being the cauſe of this miſchief, but cannot ſpeak affirmatively on this point. It has been abſurdly ſuppoſed to affect thoſe who conſume the bread made from grain thus diſeaſed with a ſort of dry gangrene in the extreme parts of the body. The nature of this diſeaſe in grain, like thoſe of many others, is ſtill far from being fully inveſtigated, ſo as to form any correct notion of the means of removing or preventing it.

Spurs, in *Old Fortifications,* denote walls that croſs a part of the rampart, and join to the town-wall.

Spurs, in *Ship-Building,* large pieces of timber, the lower ends of which are fixed againſt the ſide of the bildge-ways, and the upper ends fayed and bolted to the ſhip's ſide, to ſupport the ſhip in launching. They have been much diſcontinued of late years.

Spur-*Shell,* a ſpecies of the cochlea.

SPURGE, in *Botany.* See Euphorbia.

Spurge-*Laurel,* or *Mezereon, Laureola,* or *Daphne.* See Daphne, and Daphne *Mezereum.*

Spurge, *Olive,* the Engliſh name of a genus of plants, called by ſome botaniſts *chamelæa;* which ſee.

Others have made the olive ſpurge a ſpecies of euphorbia, or ſpurge. See Euphorbia.

Spurge, *Sun,* a name by which ſome call ſeveral ſpecies of *tithymalus;* which ſee.

Spurge-*Root,* in the *Materia Medica.* See Esulæ *Radix.*

SPURGEN, in *Geography,* a town of America, in North Carolina; 22 miles N.N.E. of Saliſbury.

SPURIOUS Diseases, in *Medicine,* are ſuch as, in ſome ſymptoms, cannot be brought under any diſtinct head, and, therefore, are called by the name of others with which they moſt agree. Whence, alſo, they are often denominated *baſtards, nothi.*

Such are a ſpurious or baſtard pleuriſy, a ſpurious peripneumony, a baſtard quinſey, and the like. See Pleurisy, Peripneumony, &c.

Spurious *Fleſh,* is an appellation given by ſome to the fleſh of the lips, gums, and that of the glands, &c.

Spurious *Medals.* See Medals.

Spurious *Ribs.* See Ribs.

Spurious *Suture.* See Suture.

SPURKETS, in a *Ship.* See Spirketting.

SPURN Head, in *Geography,* a cape of England, at the S.E. extremity of the county of York, at the mouth of the Humber, on which is a light-houſe. N. lat. 53° 38'. E. long. 0° 18'.

SPURNESS, the ſouth cape of Sunda, one of the Orkney iſlands. N. lat. 59° 7'. W. long. 2° 35'.

SPURNWATER, in *Ship-Building,* a channel left above the ends of a deck, to prevent the water from coming any further.

SPURRE, in *Ornithology,* a name given by many to the bird more commonly called the ſea-ſwallow.

SPURREY, in *Botany.* See Spergula.

Spurrey, *Corn,* in *Agriculture,* the common name of a plant of the weed kind, which is common in many parts and ſituations. It ſeldom riſes above ſix inches in height, flowers in the beginning of July, ripens its ſeed in Auguſt, and is an annual plant. When it is troubleſome as a weed, the beſt method of exterminating it is by ſummer fallows, and cutting it down before it can ſcatter its ſeeds, which are very ſmall.

Two ſpecies of this plant, however, are ſaid to be cultivated in Holland and Flanders, for the winter food for cattle, when there is a ſcarcity of graſs. It is ſaid to enrich the milk of cows, ſo as to make it afford excellent butter; and the mutton fed on it is preferable to that fed on turnips. Hens eat this plant and its ſeeds greedily, and they are ſuppoſed to make them lay a great number of eggs.

It is a plant which is ſown twice a year; the firſt time in April and May, to be ready in June or July; and the ſecond time after the rye-harveſt, to ſerve the cattle in November and December. The uſual allowance of ſeed is about twelve pounds to the acre.

It is ſaid, that though not cultivated in the county of Berks, it grows there in an abundant manner, and that the ſeeds of it might be eaſily collected in any quantity. The cultivation of it has been recommended, by way of trial, on the poor ſoils about Friliham and Yattendon, in the above diſtrict, by the writer of the account of the agriculture of the county, on the ſuggeſtion of an intelligent perſon. It is ſtated alſo, that Roucel, in his "Flora du Nord de la France," has conſidered it as an excellent late fodder for cows; and that it is made uſe of in the above countries, as well as in Germany, both in its green ſtate, and when made into hay.

It is likewiſe ſuggeſted, that as the knotted ſort of ſpurrey, though perhaps not equally grateful to animals, naturally over-runs the peat-pits in the Kennets, in the above county, it might therefore be ſown with certain effect in ſuch ſituations.

Spurrey, *Purple,* an annual weed in dry ſandy meadows, and corn-fields of the ſame dry quality. There are other ſorts which are troubleſome in wet hedges and woodlands.

SPUR-WAY, in *Rural Economy,* a term applied to a bridle, or horſe-way, or road through incloſed lands or fields, and free to any one to ride in by right of cuſtom or uſage.

SPUR-WING, in *Geography,* a river of America, in the ſtate of Maine, which runs through Scarborough, W. of Cape Elizabeth, and is navigable a few miles for veſſels of 100 tons.

SPUTT, a river of England, in the county of Weſtmoreland, which runs into the Ken.

SPUTUM, in *Medicine,* &c. the ſpittle or excrement voided at the mouth. See Saliva.

An examen of the ſputum is of great conſequence in phthiſical caſes: and Bennet, in his "Theatrum Tabidorum," applies himſelf in a particular manner to it. The *ſputum ſanguinis* is a very dangerous ſymptom in that diſeaſe.

SPY, a perſon paid to watch the actions, motions, &c. of another, particularly as to what paſſes in an army.

The uſe of ſpies is a kind of clandeſtine practice or deceit in war. Spies are generally puniſhed capitally, and immediately when they are diſcovered in a camp; and, ſays Vattel, not unjuſtly, there being ſcarcely any other way to prevent the miſchief they may do. For this reaſon, a man of honour, who would not expoſe himſelf to die by the hand of a common executioner, ever declines ſerving as a ſpy; he counts it beneath him, as it can ſcarcely be done without ſome kind of treachery. The ſovereign, therefore, cannot lawfully require ſuch a ſervice from his ſubjects, unleſs in ſome ſingular caſe, and that of the laſt importance. The mercenaries are allured to it by great rewards. If thoſe whom a ſovereign employs make a voluntary offer, or if they be not the enemy's ſubjects, or have no connection with him, he may unqueſtionably make uſe of their ſervice, without offence to juſtice or honour; but it may be aſked, is it lawful, is it decent, to ſolicit the enemy's ſubjects to act as ſpies, and betray him? Let the following paragraph ſerve as a reply.

If it be aſked in general whether it be lawful to ſeduce the enemy's men, to engage them to tranſgreſs their duty by an infamous treachery? Here we muſt diſtinguiſh between what is due to the enemy, notwithſtanding the ſtate of the war, and what is required by the internal laws of conſcience, and the rules of probity. Now the enemy may be weakened by all poſſible means, provided they do not affect the common ſafety of human ſociety, as poiſon and aſſaſſination. The ſeducing a ſubject to turn ſpy, that of a governor to deliver up his place, does not ſtrike at the foundation of the common ſafety and welfare of ſociety. Subjects acting as the enemy's ſpies, are not a fatal and inevitable evil, they may in ſome meaſure be guarded againſt; and as to the ſecurity of fortreſſes, it is the ſovereign's concern to chooſe proper governors. Thus theſe means are not contrary to the external law of nations, nor can the enemy complain of them as odious proceedings. Accordingly, they are practiſed in all wars. But are they juſt, and compatible with the laws of a pure conſcience? Certainly not. And of this the generals themſelves are ſenſible, as they are never heard to boaſt of having practiſed them. Seducing a ſubject to betray his country, ſuborning a traitor to ſet fire to a magazine, practiſing on the fidelity of a governor, inticing him, perſuading him to deliver up a place, is prompting ſuch perſons to commit deteſtable crimes. Is it honeſt to incite our moſt inveterate enemy to be guilty of a crime? If ſuch practices are at all excuſable, it can be only in a very juſt war, and for ſaving our country, when threatened with ruin by a lawleſs conqueror. The guilt of a ſubject or general who betrays his prince in a cauſe manifeſtly unjuſt, does not appear ſo very odious. He who himſelf tramples upon juſtice and probity, deſerves, in his turn, to feel the effects of perfidy and wickedneſs. And if ever it is excuſable to depart from the ſtrict rules of probity, it is againſt ſuch an enemy, and in ſuch an extremity. Vattel's Law of Nations, b. iii. ch. 10.

Wicquefort ſays, an ambaſſador is an honourable ſpy, under the protection of the law of nations.

SPYCKENS, in *Geography*, a town in the iſland of Voorn; 9 miles E. from the Brill.

SPYRUS, the *dung of goats*. This is uſually found in ſmall round maſſes, and is recommended by Hippocrates as a fumigation in the diſeaſes of the womb.

SQUACCO, in *Ornithology*, the name of a large bird of the heron kind. Its head and neck are variegated with black, white, and yellow, and it has on the back part of its head a creſt of the ſame colour. Its back is of a ferruginous yellow, its breaſt and belly are white, as are alſo its wings and tail, at leaſt in great part, and its legs are green. It is a bold and fierce bird.

SQUAD, in *Military Language*, a diminutive of ſquadron; uſed to denote any ſmall number of men, horſe or foot, that are collected together for the purpoſes of drill, &c. See Escouade.

Hence, to *ſquad* is to divide a troop or company into certain parts, in order to drill the men ſeparately, or in ſmall bodies, or to put them under the direction and care of ſome ſteady corporal, or lance corporal. Each troop ought to be divided into two ſquads, when under 40, and into three, or even four, when above this number, with an equal proportion of non-commiſſioned officers in each: and when the eldeſt is on duty, the charge of the ſquad falls on the next in the ſquad, and ſo on. Recruits ſhould always be quartered and ſquadded with old ſoldiers, who are known to be ſteady and well behaved; and thoſe men that are at all irregular in their conduct, muſt be ſeparated and diſtributed in ſquads which are compoſed of good old ſoldiers.

Squad, *Aukward*, conſiſts not only of recruits at drill, but of formed ſoldiers, that are ordered to exerciſe with them, in conſequence of ſome irregularity under arms. The term has likewiſe been uſed, by way of ridicule or reproach, to mark out thoſe officers who are negligent of their duty.

SQUADRON, a body of horſe, whoſe number of men is not fixed, but is uſually from eighty to a hundred and twenty men.

The word is formed from the Italian *ſquadrone*; of the Latin *ſquadro*, uſed by corruption for *quadro*: in regard, at firſt, the ſquadrons were always ſquare, and called alſo by the Latins *agmina quadrata*.

The ſquadron uſually conſiſts of two troops, and each troop of about forty men; a greater number cannot be advantageouſly poſted, nor have room to act in narrow grounds, woods, marſhes, defiles, &c.

The eldeſt troop takes the right of the ſquadron, and the ſecond the left.

Squadron *of Ships*, denotes either a detachment of ſhips employed on any particular expedition, or the third part of a naval armament.

The number of ſhips in a ſquadron is not fixed: a ſmall number of veſſels, if they be in a body, and have the ſame commander, may make a ſquadron.

If there be a great number, they are uſually divided into three ſquadrons; and if the ſquadrons be numerous, each ſquadron is divided into three diviſions, diſtinguiſhed by their flags and colours. See Division and Fleet.

SQUAIOTTA, in *Ornithology*, the name of a bird of the heron kind. Its beak is yellow, but blackiſh at the extremity; its legs are green; its head is variegated with grey and black; and its back very elegantly with white and red. It ſeems to have had its name from its note, which it often repeats in flying.

SQUALL, in *Sea Language*, a ſudden and violent blaſt of wind, uſually occaſioned by the interruption and reverberation of the wind from high mountains. Theſe are frequent in the Mediterranean, particularly in the Levant, as produced by the repulſion and new direction which the wind meets with in its paſſage between the various iſlands of the Archipelago. Falconer.

SQUALLEY, a note of faultineſs in the making of cloth. 43 Eliz. cap. 10. Blount. Cowel. See Rewey.

SQUALLY, in *Agriculture*, a term provincially applied to ſuch crops of turnips, corn, rape, &c. as are broken or detached by vacant or unproductive ſpots or patches. Crops which are thus produced have an extremely diſagreeable appearance, and are never promiſing or productive to the farmer.

SQUALLY *Land*, a term ſometimes applied to that ſort of ground which is of the irregularly wet thin kind.

SQUALUS, the *Shark*, in *Ichthyology*, a genus of fiſhes of the order Chondropterigious, or, according to more modern naturaliſts, of the Cartilaginous order: the generic character is as follows. The mouth is ſituated beneath the anterior part of the head, with numerous teeth diſpoſed in rows. On each ſide the neck, in moſt of the ſpecies, there are five ſpiracles of a ſemilunar ſhape. The body is oblong, and ſomewhat cylindrical.

The animals of this genus are altogether marine; and are ſaid to be rarer in the Baltic than in any other ſea: they are viviparous, and are obſerved to produce more young at a time than the rays; but each is included, as is the caſe with thoſe fiſhes, in a quadrangular capſule or involucrum, each extremity of which is extended into a long, contorted, cartilaginous thread of great length. Many of the ſharks are ſaid to emit a phoſphoric light during the darkneſs of night: they are chiefly of a ſolitary nature, and, in general, devour, with the moſt indiſcriminating voracity, almoſt every animal ſubſtance, whether living or dead. A few ſpecies are ſaid to feed chiefly on fuci, and other marine vegetables. There are about thirty-four ſpecies enumerated by Gmelin, which are ſeparated into different ſections.

Species.

A. *With temporal Orifice and anal Fin.*

ISABELLA. The firſt dorſal fin is oppoſite the abdominal. It inhabits the ſouthern Pacific ocean, and has been obſerved about the coaſts of New Zealand. It is thirty inches long; in colour it is yellowiſh; the teeth are compreſſed, ſhort, triangular, furniſhed on each ſide the baſe with a ſmaller lobe, and diſpoſed in ſix rows; the tongue is very ſhort and thick; the dorſal fin is ſubquadrangular; the ſecond placed oppoſite the anal fin; the pectoral fins are very large; the ventral are ſeparate, and pointed behind.

* **CANICULAR**; Spotted Dog-fiſh. Noſtrils ſurrounded with a lobe and vermiform appendage; the ventral fins are diſtinct. This inhabits moſt ſeas, is about four or five feet long, is very voracious, and feeds chiefly on fiſh; the body is of a reddiſh-brown, with large diſtinct ſpots, which are black above, but white beneath, a little compreſſed at each end: the ſkin when dried is uſed for various purpoſes. The head is ſmall; ſnout ſhort; eyes oblong; pupil ſea-green, iris white; the mouth is wide and oblong, with three rows of teeth; the tongue is cartilaginous, and with the palate rough; the vent is before the middle of the body; the firſt dorſal fin behind the ventral, the ſecond leſs, and nearly oppoſite the anal; the tail is narrow, ending below in a ſharp angle.

* **CATULUS**; Leſſer Spotted Dog-fiſh. This ſpecies is ſpecifically deſcribed as having noſtrils covered with a lobe and vermiform appendage; the ventral fins are connected. It inhabits the Northern, Mediterranean, and Indian ſeas. Its habit is rather ſlender; in length it is from two to three feet; the head is large; ſnout prominent, and ſlightly pointed; the ſkin is rough; the body cylindric; the colour pale brick-red, marked with very numerous, ſmall, rounded, blackiſh or duſky ſpots; the abdomen is whitiſh; both the dorſal fins are placed much nearer to the tail than the head; the ventral fins are connate, large, and of a ſlightly pointed form; the anal fin is ſmall; the tail is long, bilobate, with the lower lobe continued to a conſiderable diſtance beneath. It is a moſt voracious fiſh. According to Mr. Pennant, it breeds from nine to thirteen young at a time; it is numerous on our own coaſts, and very injurious to the fiſheries. The liver, when taken or taſted as food, is highly noxious, cauſing a long-continued ſtupor, ſucceeded by an univerſal itching, with a total peeling off of the cuticle.

STELLARIS. Lobes of the noſtrils double. This is found in the European ocean, and is from two to ſix feet long; it feeds chiefly on cruſtaceous animals, molluſcæ, and leſſer fiſh; the body is reddiſh, with unequal blackiſh ſpots; beneath it is of a dirty aſh, and reſembles the S. canicula, but the ſpots are larger and fewer; the ſnout is a little longer, the tail ſomewhat ſhorter, and the noſtrils nearly cloſed; it brings forth about twenty at a time. The dorſal fins are equal; the firſt a little behind the middle of the body, the ſecond a little behind the anal.

* **GALEUS**; Tope. Teeth nearly triangular, ſerrate on the inner edge. This ſpecies is of conſiderable ſize, often meaſuring ſeveral feet in length, though the ſpecimens uſually ſeen about the Britiſh coaſts ſcarcely exceed the length of about five feet. In its habits it reſembles the white SHARK (which ſee), being a very bold and rapacious fiſh, attacking ſuch as happen to be accidentally expoſed to it with great violence and rapidity; its ſhape is rather ſlender; its colour pale cinereous above, and whitiſh beneath; the noſe is long, flat, and pointed; the noſtrils are ſituated near the mouth, and behind each eye is a ſmall orifice; the teeth are numerous, diſpoſed in three rows, ſmall, very ſharp, triangular, and ſerrate on their inner edge. The firſt dorſal fin is placed about the middle of the back, and is rather large; the ſecond is ſmall, and ſituated near the tail, which is ſmall, and terminates in two unequal lobes, of which the lower is the broadeſt. It has been aſſerted by able and well-informed naturaliſts, that this fiſh is ſo bold as to purſue its prey to the very edge of the ſhore, and even to attack thoſe who are walking near the water's edge. It is ſuppoſed to be the fiſh mentioned by the name of *canicula*, which is deſcribed as highly dangerous to thoſe employed in diving for corals, ſponges, &c.

* **MUSTELUS**; Smooth Hound. The teeth of this ſpecies are very ſmall and obtuſe; it has ſhort pectoral fins. The fiſh of this ſpecies are of a ſlender habit; their ſnouts are ſlightly ſharpened, and lengthened; the firſt dorſal fin is large, and placed nearly in the middle of the back; the ſecond nearly oppoſite the anal fin; the tail is ſhaped as in moſt others of this tribe, or ſlightly bilobate; the lower lobe is continued to ſome diſtance beneath; the teeth are very numerous, ſmall, ſlightly convex, and ſet as in RAYS (which ſee.) The general colour of the animal is of a greyiſh-brown, paler or whiter beneath; ſometimes varies in being marked above by numerous white ſpots. The ſtomach in this fiſh is furniſhed with ſeveral appendices, ſituated near the pylorus; it is found on our own coaſts, and in other European ſeas, and alſo in the Indian ſea, and when full grown it is about two feet long.

CIRRATUS. The noſtrils have a worm-ſhaped appendage. This ſpecies inhabits the American and Pacific ſeas, and is from one to five feet long; the body is coated with large flat ſhining ſcales; when young it is ſpotted with black. The head is depreſſed; the ſnout is ſhort, obtuſe; the eyes and temporal orifice ſmall; lips thick at the ſides; teeth numerous, ſharp, long, dilated at the baſe; the two hindmoſt ſpiracles are approximate; the vent is in the middle; the firſt dorſal fin is oppoſite the ventral; the anal is ſmall; the tail is about a quarter as long as the body.

BARBATUS. The gape of the mouth is bearded with vermiform appendages. It is found about the coaſts of New Holland, and is from three to four feet long; the body is covered with ſmall, hard, ſmooth ſhining ſcales, and marked with black ſpots, round and angular, ſurrounded with a white circle. The head is large, depreſſed, and ſhort; the teeth are lanceolate, in many rows; cirri unequal, about an inch and a half long, and branched before. The temporal orifice is large; vent in the middle; firſt dorſal oppoſite the vent; the tail ſubdivided.

Tigrinus. Tail elongated; the two hindmoſt ſpiracles are confluent. It inhabits the Indian ocean, and grows to the length of fifteen feet; the body is thick, oblong, black, with irregular white ſpots and bands; feeds on teſtaceous animals and crabs. The head of this ſpecies is broad, flat, and ſloping on the fore-part; the mouth tranſverſe, with two cirri; the upper lip is thick and prominent; the teeth are minute, thoſe on the upper jaw are moveable, and rough like a raſp; the tongue is thick, ſhort; the eyes are ſmall, oblong, and the pupil is blue; the iris is black; belly broad; pectoral fins ſhort, broad; firſt dorſal oppoſite the ventral; the ſecond is oppoſite the anal; the tail is compreſſed on each ſide, thin like a leaf at the end; the fin is long, and notched at the tip.

Africanus. Body with ſeveral parallel, longitudinal, blackiſh bands above. This, as its ſpecific name imports, is found in the African ocean, and is about two feet and a half long; the body is covered with minute ſubquadrate ſcales; above it is glaucous, beneath whitiſh.

Ocellatus. On each ſide of the neck is a large, round, black blotch, ſurrounded with white. It inhabits the Pacific ocean and New Holland, is two feet and a half long; the body is long, cinereous, dotted; beneath it is of a greeniſh-aſh colour.

Zygæna. Head very broad, hammer-ſhaped. It inhabits the Mediterranean, American, and Indian ſeas; grows to ſix feet long, and to the weight of five hundred pounds; it is the moſt rapacious of all its tribe. See Shark.

Tiburio. The head is very broad, heart-ſhaped. It inhabits the South American ſeas. It very much reſembles the laſt, except that the head, inſtead of being widened on each ſide into a long proceſs, is rather ſubtriangular, and rounded off in front; the fins are glaucous.

Griseus. Spiracles ſix on each ſide. It inhabits the Mediterranean; is two feet and a half long; the body is of a mouſe colour, a little rough; in the dried ſkin there is the appearance of ſmall ſcales, with an elevated line in the middle.

Vulpes; Sea-fox, or Long-tailed Shark. This ſpecies inhabits the Mediterranean ſea, and often wanders on the Britiſh coaſts; is ſeven feet long; the body above is of a blueiſh-aſh colour; beneath it is paler; the ſcales are very minute. This is a very voracious fiſh. It is diſtinguiſhed by its plump, ſhort, ſubovate body, and very long tapering tail; the head is ſmall and pointed; the firſt dorſal fin is triangular, and placed on the middle of the back; the ſecond is ſet above the beginning of the tail, which gradually tapers to the tip, and is furniſhed with a ſhallow fin or proceſs beneath, running from the baſe to the tip, which is ſharp and ſlightly bilobate; the pectoral fins are of conſiderable ſize; the eyes are large; the mouth ſmall; the teeth triangular, ſmall, and diſpoſed in three rows. The colour of the fiſh is duſky aſh above, and whitiſh beneath. It grows to the length of thirteen or fourteen feet; the tail meaſures more than half the length of the whole animal. It is an inhabitant of the Mediterranean and other ſeas, and is conſidered as a voracious and artful fiſh; but the name of ſea-fox is applied to it rather from the length of its tail than from its ſuppoſed ſagacity.

Longicaudus. Upper jaw with two cirri; the tail is long, as its ſpecific name denotes; the head is obtuſe; the noſtrils near the mouth; there are four ſpiracles.

Appendiculatus; Botany Bay Shark. Upper jaw with two jagged, cartilaginous appendages, and four others on each ſide between the firſt and the ſpiracles. This inhabits New South Wales; is nineteen inches long; the body is brown, with three rows of large pale ſpots, dark within, rounded and nearly equal for half its length, and then growing ſuddenly very ſmall. It is an extremely fierce animal. The head is broad, but angular; the mouth is placed near the end of the head; it has nine teeth in front, which are ſharp, crooked, and in three rows, with a great number of ſmall ones on each ſide; the eyes are projecting; dorſal fins placed far back; the pectoral near the ſpiracles; ventral near the middle of the body; the anal more than half way between the laſt and the tail, with a fin-like projection behind it to the end of the tail.

B. *With the anal Fin, but no temporal Orifice.*

* Glaucus; Blue Shark. The ſides of the tail are ſmooth; the lower part of the back with a triangular dent. This is found in our own and almoſt all other ſeas. See Shark.

* Cornubicus; Probeagle Shark. The ſnout of this ſpecies is projecting, ſharp; body round, depreſſed and angulate near the tail. It inhabits the Britiſh coaſts; is from three to four feet long; the body above is of a deep blue, beneath it is ſilvery; round, except near the tail, where it is depreſſed. This ſpecies is ſlightly deſcribed by Pennant, from an engraving which he found in Borlaſe's Hiſtory of Cornwall, which was copied by Mr. Jago, who was eſteemed a very obſervant and ſkilful ichthyologiſt. A ſpecimen obſerved in 1793, on the coaſt of Haſtings, is deſcribed in the third volume of the Linnæan Tranſactions. Its length from the tip of the ſnout to the extremity of the tail, was three feet ten inches; the colour of the body was a deep blue on the back, and white or ſilvery beneath; the ſhape was round, except for about ſix inches from the tail, where it was depreſſed; at about an inch from the tail was a ſemilunar or lunar impreſſion, the points of which were towards the tail; where the body was depreſſed, the ſides were raiſed into a ſharp angle or elevated line, of about eight inches in length, running to the middle of the tail, or a little beyond; the noſe was prominent, and ſharp; and on either ſide, from the noſe to the eyes, were numerous perforations or minute pores; the tail was of a lunar form, the upper lobe nearly a third longer than the lower.

* Cambricus; Beaumaris Shark. Snout ſhort, blunt; body cylindrical, angulate near the tail. This is chiefly found on the Britiſh coaſts; is ſeven feet long; very much reſembles the laſt, except that it does not taper ſo much towards each end; the body is of a lead-colour, and ſmoothiſh.

Cinereus. Seven ſpiracles on each ſide. It inhabits the Mediterranean; is three feet long; the body is glaucous, and a little rough.

* Maximus; Baſking Shark. Teeth conic, not ſerrate. See Shark.

* Carcharias; White Shark. In this ſpecies the teeth are triangular. This is the moſt dreadful and voracious of all animals. See Shark.

C. *With temporal Orifice, but no anal Fin.*

* Spinosus. Body covered over with large mucronate

tubercles. This is about four feet in length; the colour is grey-brown above, whitiſh beneath; the body is roughened with ſcattered unequal tubercles, conſiſting of a broad round baſe, and curved, ſharp-pointed tip; in ſome they are bifid; eyes large; ſnout prominent and conic; its gape is moderate; the teeth of a ſquariſh ſhape, compreſſed, cornered at the margins, and placed in ſeveral rows; dorſal fins placed near the tail, the firſt oppoſite the ventral, which are ſet at an unuſual diſtance from the head, and are almoſt as large as the pectoral; the tail is angular.

* ACANTHIAS; Picked Dog-fiſh. Dorſal fins ſpinous; the body is roundiſh; a variety has an ocellate body. This ſpecies inhabits moſt ſeas; it is about three feet and a half long; the body above is blackiſh, dotted ſparingly with white; the ſides are white, inclining to violet, with a few angulate tranſverſe furrows, beneath white; the fleſh is often ſalted and eaten.

JACKSONII. Eyes with a prominence over them on each ſide; before each of the dorſal fins is a ſtrong ſpine. This inhabits Port Jackſon, New Holland. It is not more than two feet long; the body is tapering, ſkin rough, above brown, beneath paler; the head is ſomewhat convex; teeth numerous, in many rows, larger as they are placed backwards, forming a bony plate.

SPINAX. Body beneath blackiſh. It is found in the Indian ocean; and, in its ſpinous back-fins, it very much reſembles the laſt.

SQUAMOSUS. Body coated with ſmall oblong ſcales. The body of this is three feet long, thick, round, reſembling the next, except in having a longitudinal elevated line of ſcales down the middle.

CENTRINA. Body nearly triangular. It is from three to four feet in length; the body above is brown, carinate, beneath whitiſh, broad; ſkin covered with hard, erect tubercles; the fleſh is very hard.

INDICUS. Back variegated, unarmed; teeth acute. It inhabits the Indian ocean.

AMERICANUS. Dorſal fins unarmed, the hinder one larger, ventral large near the tail. It is found in the South American ſeas; is three feet long; body round; ſcales ſmall, angular.

* SQUATINA; Angel Fiſh. Pectoral fins very large, and notched on the fore-part. This ſpecies inhabits the Northern ſeas, and is from ſix to eight feet long; it feeds on leſſer fiſh, and brings forth thirteen young at a time. The body above is cinereous, rough, with ſmall recurved prickles; beneath it is ſmooth, white. In its ſhape it approaches very nearly to the Ray genus.

D. *Without Teeth.*

MASSASA. Pectoral fins long. An inhabitant of the Red ſea.

KUMAL. Pectoral fins ſhort; the mouth with four cirri. It inhabits the Red ſea.

SQUALUS is alſo a name given by Varro, Columella, Salvian, and others, to a ſpecies of cyprinus, diſtinguiſhed by Artedi by the name of the oblong cyprinus with long ſcales, and with the pinna ani containing eleven rays, and commonly known with us under the name of *chub* or *chevin*.

The generality of authors call it *capito* and *cephalus*, but it is very improper to give diſtinct generical names to fiſh, which are genuine ſpecies of other genera.

The name ſqualus is originally Latin; it is uſed by Pliny, and many other of the old Roman authors, and is derived from the word *ſqualor*, becauſe this fiſh is found to delight in impure and dirty places.

SQUAM, in *Geography*, an American lake, partly ſituated in the townſhip of Holderneſs in Grafton county, New Hampſhire, and partly in Strafford county; about five miles long and four broad.—Alſo, a river of New Hampſhire, the outlet of the above lake, which, after running a ſouth-weſt courſe, joins the Pemigewaſſet, at the town of New Cheſter, 10 miles above the mouth of the Winepiſcogee branch.

SQUAM *Beach*, lies on the ſea-coaſt of New Jerſey, between Barnegat inlet and Cranberry new inlet.

SQUAM *Harbour*, lies on the north-eaſt ſide of Cape Amen, in the ſtate of Maſſachuſetts. *Squam* (Pidgeon-hill) lies in N. lat. 42° 40′. W. long. 70° 36′.

SQUAMARIA, in *Botany*, from *ſquama*, a ſcale, in alluſion to its ſcaly root, or ſubterraneous ſtem, is Rivinus's appellation for the Toothwort (ſee LATHRÆA); and is ſtill uſed generically by Haller and Scopoli, though only ſpecifically by Linnæus. The ſcales in queſtion, bearing a great reſemblance in every thing but hardneſs to the human fore-teeth, have given riſe to the Engliſh name, and to that of *Dentaria*, uſed by Matthiolus. But this plant muſt not be confounded with the Linnæan DENTARIA. See that article.

SQUAMIS, in *Ichthyology*, a name given by Albertus, and others, to the fiſh called by us the monk, or angel-fiſh, by the generality of authors *ſquatina*, and by the old Greek writers *rhine*. See SQUALUS.

SQUAMOSÆ *Suturæ Additamentum*, in *Anatomy*, the portion of ſuture which connects the poſterior inferior length of the parietal to the maſtoid part of the temporal bone. See CRANIUM.

SQUAMOSE CULM, among *Botaniſts*. See STALK.

SQUAMOSE *Root*, one compoſed of, or covered with leſſer flakes. See ROOT.

SQUAMOUS, in *Anatomy*, a ſuture of the head, made by the thin edge of one bone overlapping a correſponding thin edge of another.—Alſo, the portion of the temporal bone entering into the formation of the *ſquamoſæ ſuturæ additamentum*. See CRANIUM.

SQUARCIONE, FRANCESCO, in *Biography*, a painter, born at Padua in 1394, more and better known as the founder of a ſchool of art, than for any particular works of his own production. The ſchool he maintained was furniſhed with deſigns and veſtiges of antiquity, which he had acquired not only in Italy, but alſo in Greece, whither he travelled for the purpoſe; and it was at one time attended by upwards of 130 ſtudents, ſo that he acquired from it the reſpectable title of the father of the young painters. One picture of his is more particularly noticed by Lanzi, which was formerly in the church of the Carmelites at Padua, and afterwards in the private poſſeſſion of the Conte de Lazara, repreſenting St. Jerome ſurrounded by three ſaints; and he ſpeaks of it in terms of praiſe for ſo early a production. It was painted, according to an inſcription upon it, for the noble family of Lazara, in 1452, and is ſigned Franceſco Squarcione. He died in 1474, at the age of 80.

SQUARE, QUADRATUM, in *Geometry*, a quadrilateral figure, whoſe angles are right, and ſides equal.

SQUARE, *To find the Area of a.* Seek the length of one ſide; multiply this by itſelf; and the product is the area of the ſquare. Thus, if the length of a ſide be 345, the area will be 119025; and if the ſide of a ſquare be 10, the area will be 100.

Since, then, a decempeda contains 10 feet, a foot 10 digits, &c. a ſquare decempeda contains 100 ſquare feet, a ſquare foot 100 ſquare digits, &c.

SQUARE, *the Properties of a*, are, that its angles are all right, and, conſequently, its ſides perpendicular; that it is divided into two equal parts, by a diagonal; that the diagonal of a ſquare is incommenſurable to the ſide.

SQUARES, *for the Ratio of.* They are to each other in the duplicate ratio of their ſides. *E. gr.* a ſquare whoſe ſide is double another, is quadruple of that other ſquare.

SQUARE *of the Cube.*
SQUARE *of the Surdeſolid.* } See POWER.

SQUARE *Number,* in *Arithmetic* and *Algebra,* is the product ariſing from multiplying any number by itſelf. Thus, $9 = 3.3$, $16 = 4.4$, $25 = 5.5$, &c. are ſquare numbers: and ſince, by the rules of algebra, $-3 \times -3 = 9$; $-4 \times -4 = 16$; $-5 \times -5 = 25$, &c.; it follows, that the ſquare root of every poſitive number has two different roots; the one *plus,* or affirmative; the other *minus,* or negative; while the ſquare root of every negative number is imaginary, or impoſſible.

Square numbers have ſeveral remarkable properties, of which the following are ſome of the moſt intereſting, *viz.*

1. Every ſquare number is of one of the forms $4n$ or $4n + 1$; that is, every ſquare, when divided by 4, will leave either 0 or 1 for a remainder: and underſtanding this expreſſion ſtill in the ſame ſenſe, the following table will expreſs the forms of ſquare numbers to the moduli, or diviſors, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12.

Moduli.	Poſſible Forms of Squares.				
3	$3n$	$3n + 1$			
4	$4n$	$4n + 1$			
5	$5n$	$5n \pm 1$			
6	$6n$	$6n + 1$	$6n + 3$	$6n + 4$	
7	$7n$	$7n + 1$	$7n + 2$	$7n + 4$	
8	$8n$	$8n + 1$	$8n + 4$		
9	$9n$	$9n + 1$	$9n + 4$	$9n + 7$	
10	$10n$	$10n \pm 1$	$10n \pm 4$	$10n \pm 5$	
11	$11n$	$11n + 1$	$11n + 3$	$11n + 5$	$11n + 9$
12	$12n$	$12n + 1$	$12n + 4$	$12n + 9$	

2. And hence, by excluſion, we may derive the following table of impoſſible forms, *viz.*

Moduli.	Impoſſible Forms for Squares.				
3	$3n + 2$				
4	$4n + 2$	$4n + 3$			
5	$5n + 2$	$5n + 3$			
6	$6n + 2$	$6n + 5$			
7	$7n + 3$	$7n + 5$	$7n + 6$		
8	$8n \pm 2$	$8n \pm 3$	$8n + 7$		
9	$9n + 2$	$9n \pm 3$	$9n + 5$	$9n + 8$	
10	$10n \pm 2$	$10n \pm 3$			
11	$11n + 2$	$11n + 6$	$11n + 7$	$11n + 8$	$11n + 10$
12	$12n \pm 2$ $12n + 10$	$12n + 3$	$12n \pm 5$	$12n + 6$	$12n + 8$

Theſe formulæ, as they involve no higher power of the indeterminate n than the firſt, are called *linear* forms; but, by means of them, we eaſily arrive at a variety of *quadratic* formulæ, which it is extremely uſeful to be acquainted with, in practiſing the Diophantine or indeterminate analyſis.

If a perſon, unacquainted with theſe excluſions, were required to find two ſuch numbers, that double the ſquare of the one, added to triple the ſquare of the other, ſhould be a ſquare, he would ſee nothing impoſſible in the propoſition, and might, therefore, loſe many uſeleſs hours in the reſearch; whereas, by a little attention to the impoſſible and poſſible forms, he would find the problem abſolutely impoſſible, and hence ſpare himſelf much uſeleſs labour.

3. The method of deducing impoſſible quadratic forms from the linear ones above given, will be ſeen immediately from a ſingle example. Let it be required to aſcertain whether the equation, $2x^2 + 3y^2 = w^2$, be poſſible or impoſſible. Firſt, we may aſſume x, y, and w, prime to each other; for if x and y have a common diviſor, w muſt have the ſame, and the whole equation may be divided by it; whereby it will be reduced to another equation $2x'^2 + 3y'^2 = w'^2$, in which theſe quantities have no longer a common diviſor, or, in other words, they are prime to each other.

Since, then, x and y are prime to each other, they cannot be both of the form $3n$; for, in this caſe, they would have a common diviſor 3. Let then, firſt, x^2 be of the form $3n$, and y^2 of the form $3n + 1$; then $2x^2$ is of the form $3n'$, and $3y^2$ of the form $3n' + 3$, and conſequently their ſum will have the form $3n$, which is impoſſible, becauſe, in this caſe, w and x would have a common diviſor 3; and if we ſuppoſe x^2 of the form $3n + 1$, and y^2 of the form $3n$; then $2x^2 + 3y^2$ is of the form $3n + 2$, which is an impoſſible form: and, laſtly, if we aſſume both of the form $3n + 1$, then $2x^2 + 3y^2$ would have again the ſame impoſſible form $3n + 2$; therefore, in no caſe can $2x^2 + 3y^2 = w^2$ be poſſible in integral numbers.

In the ſame manner a variety of other impoſſible forms may be deduced, of which the following are thoſe which moſt commonly occur.

(5) *Modulus* 3.

$$2t^2 + 3u^2 = w^2$$
$$5t^2 + 3u^2 = w^2$$
$$8t^2 + 3u^2 = w^2$$
$$(3p + 2)\,t^2 + 3u^2 = w^2$$

(6) *Modulus* 5.

$$2p^2 \pm 5u^2 = w^2$$
$$3p^2 \pm 5u^2 = w^2$$
$$7t^2 \pm 5u^2 = w^2$$
$$(5p \pm 2)\,t^2 \pm 5u^2 = w^2$$

Or the two latter general forms may be rendered more comprehenſive, by the introduction of another indeterminate q; obſerving only that, in this caſe, the quantity muſt always be prime to the modulus. With this condition, the two latter may be written thus:

$$(3p + 2)\,t^2 + 3qu^2 = w^2, \text{ and}$$
$$(5p \pm 2)\,t^2 \pm 5qu^2 = w^2.$$

(7) *Modulus* 7.

$$(7p + 3)\,t^2 \pm 7qu^2 = w^2$$
$$(7p + 5)\,t^2 \pm 7qu^2 = w^2$$
$$(7p + 6)\,t^2 \pm 7qu^2 = w^2$$

(8) *Modulus* 11.

$$(11p + 2)\,t^2 \pm 11qu^2 = w^2$$
$$(11p + 6)\,t^2 \pm 11qu^2 = w^2$$
$$(11p + 7)\,t^2 \pm 11qu^2 = w^2$$

(9) *Modulus* 13.

$$(13p \pm 2)\,t^2 \pm 13qu^2 = w^2$$
$$(13p \pm 5)\,t^2 \pm 13qu^2 = w^2$$
$$(13p \pm 6)\,t^2 \pm 13qu^2 = w^2$$
$$(13p \pm 7)\,t^2 \pm 13qu^2 = w^2$$

(10) *Modulus* 17.

$$(17p \pm 3)\,t^2 \pm 17qu^2 = w^2$$
$$(17p \pm 5)\,t^2 \pm 17qu^2 = w^2$$
$$(17p \pm 6)\,t^2 \pm 17qu^2 = w^2$$
$$(17p \pm 7)\,t^2 \pm 17qu^2 = w^2$$

A great variety of impoſſible forms might have been given to other moduli; but the above are ſufficient for our preſent purpoſe.

There are alſo many formulæ, which, though poſſible ſingly, become impoſſible in pairs: ſuch are the following:

$$11.\begin{cases} x^2 + y^2 = z^2 \\ x^2 - y^2 = w^2 \end{cases} \qquad 12.\begin{cases} x^2 + y^2 = 2w^2 \\ x^2 - y^2 = 2z^2 \end{cases}$$

$$13.\begin{cases} 2x^2 + y^2 = z^2 \\ 2x^2 - y^2 = w^2 \end{cases} \qquad 14.\begin{cases} x^2 + 2y^2 = 2z^2 \\ x^2 - 2y^2 = 2w^2 \end{cases}$$

$$15.\begin{cases} x^2 + 2y^2 = z^2 \\ x^2 - 2y^2 = w^2 \end{cases} \qquad 16.\begin{cases} 2x^2 + y^2 = 2z^2 \\ 2x^2 - y^2 = 2w^2 \end{cases}$$

Theſe might alſo be carried to a much greater extent, and many collateral properties drawn from them relative to the impoſſibility of ſome higher powers: we muſt not, however, carry the ſubject farther in this place. The reader, who is deſirous of more detailed information, may conſult Barlow's "Elementary Inveſtigation of the Theory of Numbers," where this part of the doctrine of numbers is carried to a conſiderable extent. We ſhall merely ſelect a few other diſtinct properties of ſquares, as they are given by the ſame author, in his "Mathematical Dictionary."

17. The ſum of two odd ſquares cannot be a ſquare.

18. An odd ſquare, taken from an even ſquare, cannot leave a ſquare remainder.

19. If the ſum of two ſquares be itſelf a ſquare, one of the three ſquares is diviſible by 5.

20. Square numbers muſt terminate in one of the digits 0, 1, 4, 5, 6, or 9.

21. No number of repetend digits can be a ſquare.

22. The area of a rational right-angled triangle cannot be equal to a ſquare.

23. The two following ſeries are remarkable for being ſuch, as, when reduced to improper fractions, the ſum of the ſquares of each numerator and denominator is a complete ſquare; or, which is the ſame, they are the ſides of rational right-angled triangles. Theſe ſeries are as follow, *viz.*

$$1\tfrac{1}{3},\ 2\tfrac{3}{5},\ 3\tfrac{3}{7},\ 4\tfrac{4}{9},\ 5\tfrac{5}{11},\ \text{\&c. \&c.}$$
$$1\tfrac{7}{8},\ 2\tfrac{11}{12},\ 3\tfrac{15}{16},\ 4\tfrac{19}{20},\ 5\tfrac{23}{24},\ \text{\&c. \&c.}$$

24. The ſecond differences of conſecutive ſquare numbers are equal to each other, thus:

Squares	1,	4,	9,	16,	25,	&c.
Firſt difference	3,	5,	7,	9,	&c.	
Second difference	2,	2,	2,	&c.		

To theſe we may alſo add the following; which are more particularly applicable to the indeterminate and Diophantine analyſis.

25. If a number be the ſum of two ſquares, its double is alſo the ſum of two ſquares; for

$$(x^2 + y^2) \times 2 = (x + y)^2 + (x - y)^2.$$

Hence alſo, the ſum of two ſquares multiplied by any power of 2, is the ſum of two ſquares.

26. The product of two numbers, each being the ſum of two ſquares, is itſelf the ſum of two ſquares; for

$$(x^2 + y^2) \times (x'^2 + y'^2) = \begin{cases} (xx' + yy')^2 + (xy' - x'y)^2, \text{ or} \\ (xx' - yy')^2 + (xy' + x'y)^2 \end{cases}$$

$$\begin{array}{ll} \text{Thus,} & 5 = 2^2 + 1^2 \\ & \underline{13 = 3^2 + 2^2} \\ \text{Product} & \underline{65 = 8^2 + 1^2 \text{ or } 7^2 + 4^2} \end{array}$$

27. The product of the ſum of four ſquares, by the ſum of four other ſquares, is itſelf the ſum of four ſquares; thus

$$(w^2 + x^2 + y^2 + z^2) \times (w'^2 + x'^2 + y'^2 + z'^2) = \begin{cases} (ww' + xx' + yy' + zz')^2 + (wx' - xw' \\ \qquad + yz' - y'z)^2 + \\ (y'w - xz' - yw' + zx')^2 + (wz' + xy' \\ \qquad - yx' - zw')^2 \end{cases}$$

as will appear by the developement of theſe formulæ.

28. Every integral number is either a ſquare, or the ſum of two, three, or four ſquares.

The latter is one of the celebrated numerical theorems of Fermat, which was firſt demonſtrated by Lagrange.

For a variety of other properties, ſee the works above referred to.

We ſhall conclude this article with a table of the ſquares and cubes of all numbers from 1 to 1200. A table of the ſquare and cube roots, to the ſame extent, is given under the article ROOT.

TABLE of Squares and Cubes to 1200.

SQUARE *Root*, a number conſidered as the root of a ſecond power or ſquare number: or a number, by whoſe multiplication into itſelf a ſquare number is generated. See ROOT.

To extract the Square Root out of any given Number, ſee EXTRACTION *of Roots*.

SQUARE, *Norma*, is an inſtrument made of wood or metal, ſerving to deſcribe and meaſure right angles; ſuch is L E M, *Plate* XIV. *Geometry*, *fig*. 10.

It conſiſts of two rules or branches faſtened perpendicularly at one of their extremes. When the two branches are moveable on a joint, it is called a *bevel*.

To examine whether or not a ſquare be exact, deſcribe a ſemicircle, A E F, of any length, at pleaſure; and therein, from each extreme of the diameter, A and F, draw right lines to a point taken at pleaſure in the periphery, as E: to the ſides of the angle, A E F, apply the ſquare, ſo as its vertex may fall on F. If this be poſſible, that ſquare is juſt.

SQUARE, *The*, an inſtrument uſed in drawing, which conſiſts of a flat ruler *h g* (*fig*. 11.), at one end of which are faſtened two tranſverſe pieces; one of them, *a b*, fixed at right angles to it, and the other, *c d*, moveable round the centre *f*, ſo as to be fixed at any angle required. Theſe tranſverſe pieces are applied cloſe to the ſide of the drawing-board, which is a ſmooth board made in the form of a ſquare, or parallelogram, while the ruler lies upon it; and by ſliding them along the board, lines may be drawn parallel to one another with much leſs trouble than by the help of a parallel ruler. By the fixed tranſverſe, lines may be drawn parallel to one ſide of the board, and perpendicular to the other; and, by the moveable tranſverſe, lines that have any degree of obliquity to the ſides of the boards, may be drawn parallel to one another: and if, without moving the tranſverſe, the ruler be removed to the other ſide of the board, lines may be drawn perpendicular to them. But if the obliquity be very great, it will be impoſſible to apply the ſquare, ſo as to interſect the lines at right angles in ſome parts of the board. In this caſe recourſe muſt be had to a parallel ruler.

SQUARE, *Geometrical*, a compartiment frequently added on the face of the quadrant, called alſo line of ſhadows and quadrant.

SQUARE, *Gunner's*. See QUADRANT.

SQUARES, *Magic*. See MAGIC *Square*.

SQUARE, in *Glaſs-Making*, an inſtrument with which the conciator, or founder, ſtirs and mixes together the metal, when in fuſion in the melting-pots. When this inſtrument is grown red-hot, it is always to be quenched in a pail of water, otherwiſe the metal will ſtick to it.

SQUARE, in the *Manege*, is uſed for working in a ſquare. The piſte or tread of a volt, inſtead of being always circular, and traced upon a circumference round a centre, ought to be imagined as if it formed four ſtraight equal lines laid in a ſquare, and equally removed from the centre or the pillar, which repreſents it in the middle of the manege-ground; ſo that, to work in a ſquare, is to ride along each of theſe four lines, turning the hand at every corner, and ſo paſſing from one line to another.

SQUARE, *The*, in the *Military Art*, a particular form into which troops are thrown on critical occaſions; particularly to reſiſt the charge of cavalry.

SQUARE *Battalion*, *Hollow*, and *Solid*. See the ſeveral articles.

SQUARE *Cap*. See CAP.

SQUARE *Character*. See HEBREW.

SQUARE *Foot*, *Nails*, *Niche*, *Pedeſtal*, *Pillar*, *Roof*, and *Winding-ſtairs*. See the ſubſtantives.

SQUARE, in *Sea Language*, a term peculiarly appropriated to the yards and their ſails, implying that they hang at right angles with the maſt or keel, or that they are of greater extent than uſual.

Thus, when the yards are ſo balanced by their lifts, as to hang at right angles with the maſt, they are ſaid to be ſquare by *the lifts*; when they hang perpendicular to the ſhip's length, they are called ſquare by *the braces*; but when they lie in a direction perpendicular to the plane of the keel, they are ſquare by *the lifts and braces*; or, in other words, they hang directly acroſs the ſhip, and parallel to the horizon.

The yards are ſaid to be very ſquare when they are of extraordinary length; and the ſame epithet is then applied to their ſails, which by conſequence acquire an additional breadth.

SQUARE *of an Anchor*, denotes the upper part of the ſhank. See ANCHOR.

SQUARE-*Body*, in *Ship-Building*, all the midſhip part of the ſhip, or that between the cant-bodies, whoſe timbers ſtand at right angles, or ſquare with the keel.

SQUARE-*Maker*, a ſhipwright, who cuts the butts of the planks when required to receive the oakum, and prepares the work ready for the caulkers.

SQUARE-*Ribbands*, the ſame as horizontal ribbands. See RIBBANDS.

SQUARE-*Rigged*, is an epithet applied to a ſhip which has long yards at right angles with the length of the deck, and low maſts; and hence it is uſed in contradiſtinction to all veſſels whoſe ſails are extended by ſtays or lateen-yards, or by booms and gaffs; the uſual ſituation of which is nearly in the plane of the keel.

Hence, ſquare-ſail is a ſail extended to a yard, which hangs parallel to the horizon, as diſtinguiſhed from the other ſails, which are extended by booms and ſtays, placed obliquely. This ſail is only uſed in fair winds, or to ſcud under in a tempeſt. In the former caſe it is furniſhed with a large additional part, called the bonnet, which is then attached to its bottom, and removed when it is neceſſary to ſcud. Falconer.

SQUARE-*Sterned*, a term applied to ſhips having broad ſterns, and the butts of the planks of the bottom ending on the wing-tranſom. All Britiſh ſhips are now built upon this principle, whilſt many of other nations are ſtill conſtructed by the ancient methods; hence we ſo frequently hear the phraſe of "ſquare-ſterned and Britiſh-built," as our practice in this reſpect juſtly claims the ſuperiority over that of all other nations.

SQUARE-*Timbers*, the timbers which ſtand at right angles, or ſquare with the keel. See SQUARE-*Body*.

SQUARE-*Tuck*, a name given to the after-part of a veſſel's bottom, when terminated in the ſame direction up and down as the wing-tranſom; and the planks of the bottom end in a rabbet at the fore-ſide of the faſhion-piece.

SQUARE *Handkerchief*, in *Geography*, a cluſter of iſlets and rocks in the Atlantic, formerly called "Bazos de Babuca;" extending above 100 miles in circumference. N. lat. 21°. W. long. 69°.

SQUARE *Iſland*, a ſmall iſland in the N. part of lake Superior. N. lat. 48° 40′. W. long. 87° 22′.—Alſo, an iſland near the E. coaſt of Labrador. N. lat. 52° 54′. W. long. 55° 34′.

SQUARING, in *Mathematics*. See QUADRATURE.

SQUARING *the Circle*, is the making a ſquare whoſe area ſhall be equal to the area of a given circle.

The beſt mathematicians have found it impoſſible to ſolve this problem ſo as to be preciſely exact; but they can eaſily come ſo near it, as not to err ſo much in the area as a grain of ſand would cover in a circle, whoſe diameter is equal to the diameter of Saturn's orbit. The following proportions are near enough to the truth for any real uſe that can ariſe from this problem.

As 100000000 is to the diameter of the given circle, ſo is 88622692 to the ſide of the ſquare required. Therefore,

If the Diameter of the Circle be	The Side of the Square will be
100000000	88622692.
10000000	8862269.2
1000000	886226.92
100000	88622.692
10000	8862.2692
1000	886.22692
100	88.622692
10	8.8622692
1	0.88622692

And, as 100000000 is to the ſide of a given ſquare, ſo is 112837917 to the diameter of a circle very nearly equal to the ſquare. Therefore,

If the Side of the Square be	The Diameter of the Circle will be
100000000	112837917.
10000000	11283791.7
1000000	1128379.17
100000	112837.917
10000	11283.7917
1000	1128.37917
100	112.837917
10	11.2837917
1	1.12837917

See CIRCLE, DIAMETER, and QUADRATURE.

SQUARTIA, in *Ichthyology*, a ſpecies of fiſh found in the Eaſt Indies, the ſkin of which makes the ſhagreen.

SQUASH GOURD, in *Gardening*, the common name of a particular ſort of gourd-plant, with erect ſtems or ſtalks. See CUCURBITA.

SQUASH *Pear-tree*. See PEAR-*tree*.

SQUATAROLA, in *Ornithology*, a name given by the Venetians to the grey plover, or *pluvialis cinerea*.

SQUATINA, in *Ichthyology*, the *monk-fiſh*, a ſpecies of the ſqualus, called, in Italian, the *peſce angelo*, and thence in Engliſh the angel-fiſh and monk-fiſh. See SQUALUS.

SQUATINATORIA, a name by which ſome authors have called the *rhinobatos*, a ſea-fiſh of a ſort of middle nature between the monk-fiſh, or angel-fiſh, and the ray.

SQUATT, in *Mineralogy*, a term given by the Engliſh miners to a peculiar ſort of bed of ore, leſs valuable than a load or vein, becauſe of its reaching but a little way.

Though the ore of the ſquatts is generally very rich and good, not inferior in quality to the beſt vein-ore, the miners are often diſappointed, on finding theſe ſquatts inſtead of the right veins, after a long ſearch. In the tin countries, the way of ſearching for mines is by looking after the SHOAD-*ſtones*, which ſee.

Theſe upper parts of the veins have been waſhed off, and carried down the ſides of the hills, in which the mines uſually lie, into the flat country; but they always lie in a regular and continued train, from the orifice of the mine to the fartheſt part of the train; ſo that when but one ſtone of this kind is found, the miners are certain of coming to the bed of metal, on tracing it up to its head by the train. This is a laborious and expenſive work, becauſe the ſtones never lie on the ſurface, but at the different depths of one to ten feet, or any depth between theſe. The ſquatts have their trains of ſhoad-ſtones as well as the regular veins, and when theſe are traced to the orifice, there is the appearance of a rich load, which the proprietor is not thoroughly undeceived in till the diggers come to the end of it.

The ſquatt is a bed of ore from three to ten fathoms long, and uſually is about half as broad as it is long; few are larger than this ſtandard, but many much leſs. This is always flat, and thence has its name; the round collections of ore of the ſame kind being called *bonnies*. The ſquatt communicates with no other load or vein, but is entire of itſelf, and its extremities terminate at once, without running into ſeveral little ſtrings, in the manner of thoſe of the right veins. It does not lie within walls, as the loads or veins always do, though it is always depoſited in the ſhelf, or faſt ground; that is, in ſtrata that have not been moved. Phil. Tranſ. N° 69.

SQUATUS, in *Ichthyology*, a name uſed by Pliny, and other of the old Roman authors, to expreſs the fiſh called by the old Greek writers *rhine*, and by the moderns *ſquatina*. See SQUALUS.

SQUIB *and Mince-meat Manures*, in *Agriculture*, are terms which are applied to thoſe ſorts which are collected in large towns, as the metropolis, and others. The former chiefly conſiſts of the more ſmall mixed powdery kinds, but the latter principally of the more reduced animal matters. They would both ſeem to be ſuperior to ſoot or malt-duſt in the trial of a writer in the Agricultural Report of the County of Middleſex. See SOOT and MANURE.

SQUIBS. See FIRE-*Works*.

SQUILACHI, in *Zoology*, the name by which the modern Greeks call the jackall, or *lupus aureus* of authors.

SQUILL. See SQUILLA.

SQUILL, *Officinal*, or *Sea-onion*, *Scilla Maritima*, in the *Materia Medica*. The roots, or rather the bulbs, of this ſpecies are the parts that are uſed in medicine. Of theſe bulbs there are two ſorts, the red and white, which are ſuppoſed to be accidental varieties; but for medicinal uſe the red is generally preferred, as it has been ſuppoſed to be more efficacious than the other. They grow naturally on ſea-ſhores, or in ditches where the ſalt-water flows in with the tide, in moſt of the warm parts of Europe; particularly on ſandy ſhores in Spain and in the Levant, from whence we are annually ſupplied with them. They ſhould be choſen large, plump, freſh, and full of a clammy juice. They are preſerved freſh in ſand; but as they are apt to ſpoil, it is beſt to keep them in the dried ſtate. However, the freſh bulb loſes in drying about four-fifths of its weight, without any conſiderable loſs of its taſte or virtue: hence four grains, which are the mean doſe of the dry bulb in powder, are equivalent to near a ſcruple of the freſh ſquill. Nevertheleſs, its acrimony, on which its virtue depends, is partially diſſipated by drying and long keeping; and completely deſtroyed by heat. The moſt convenient way of drying it is, after peeling off the outer ſkin, to cut the bulbs tranſverſely into thin ſlices, and expoſe them to a gentle warmth. The ancients, in order to abate the acrimony of the ſquill for certain purpoſes, after ſeparating the ſkin and fibres, encloſed it in a paſte made of flour and water, and then baked it in an oven, till the paſte became dry, and the ſquill thoroughly ſoft and tender. The ſquill, ſo prepared, was beaten with two-thirds its weight of flour, the mixture formed into troches, and dried with a gentle heat. Theſe troches were ſuppoſed to be alexipharmic, and on this account were uſed as an ingredient in theriaca, with which view they are ſtill retained. Water, wine, proof-ſpirit, and rectified ſpirit, extract the virtues both of the freſh and dry bulb. Nothing riſes in diſtillation with any of theſe menſtrua, the entire bitterneſs and pungency of the ſquill remaining concentrated in the inſpiſſated extracts: the ſpirituous extract is ſmaller in quantity than the watery, and its taſte is proportionally ſtronger, almoſt fiery. Alkalies conſiderably abate both the bitterneſs and acrimony of the ſquill: vegetable acids make little alteration in either of theſe reſpects. Theſe acids extract its virtue equally with watery or ſpirituous menſtrua; and, as an expectorant in diſorders of the breaſt, excellently coincide with it.

The expreſſed juice, when diluted with water, filtered, and boiled, yields white flakes of albumen. Nitrate of mercury and ſuperacetate of lead ſeparate from it white curdy precipitates. Infuſion of galls forms in it pale browniſh flakes; ſulphate of iron throws down a copious pale green precipitate: lime evolves ammonia. When the inſoluble part of dried ſquill is digeſted in muriatic acid, filtered, and ammonia added in exceſs, a copious precipitate is thrown down, which is oxalate of lime. Ether digeſted on dried ſquill acquires a pale green hue, and when evaporated on the ſurface of water, a thin pellicle of very bitter reſin is depoſited; while the water acquires an intenſely bitter taſte, and yields copious precipitates with ſolutions of acetate of lead and nitrate of ſilver. From theſe imperfect experiments, ſquills appear to contain extractive, albumen, a ſmall portion of reſin, mucus, carbonate of ammonia, the bitter principle, ſtarch, and oxalate of lime.

The root of the ſquill has been known in medicine in the early ages of Greece; ſo that the introduction of its medical uſe has been referred by ſome to Epimenides, and by others to Pythagoras. It is noticed by Dioſcorides, Hippocrates, Galen, Aëtius, Celſus, Pliny, Cælius Aurelianus, and the Arabian phyſicians. Its medical character has been retained ever ſince to ſuch a degree, that it is ſtill deſervedly held in high eſtimation, and frequently uſed. It ſeems, however, to manifeſt a poiſonous quality to ſeveral animals, as many medical writers have teſtified. If adminiſtered in large and repeated doſes, it not only excites nauſea, tormina, and violent vomitings, but it has been known to produce ſtrangury, bloody urine, hypercatharſis, cardialgia, hæmorrhoids, convulſions, with fatal inflammation and gangrene of the ſtomach and bowels. Nevertheleſs, under proper management, and in certain caſes and conſtitutions, it merits recommendation as a medicine of great practical utility, and real importance in the cure of many obſtinate diſeaſes. In ſmall doſes it is expectorant and diuretic; but in large doſes, emetic and purgative: but when theſe latter effects take place, the medicine is prevented from reaching the blood-veſſels and kidnies, and the patient derives no benefit from its diuretic efficacy. In ſuch caſes it ſhould be given in ſmaller doſes, at more diſtant intervals, or an opiate ſhould be joined to it, which, according to Dr. Cullen, will anſwer the ſame purpoſe. By repeated uſe the doſe may be increaſed, and the intervals of adminiſtering it diminiſhed; and accordingly, when the doſes are tolerably large, the opiate may be moſt conveniently employed to direct the operation of the ſquill more certainly to the kidnies. In caſes of dropſy, he ſays, when there is an effuſion of water into the cavities, and therefore leſs water paſſes to the kidnies, neutral ſalt, accompanying the ſquill, may be of uſe in determining it more certainly to the kidnies; and when it is perceived to take this courſe, he is perſuaded that it will be always uſeful, and generally ſafe, during the exhibition of the ſquills, to increaſe the uſual quantity of drink. The diuretic effects of ſquills have been ſuppoſed to be promoted by the addition of ſome mercurial; and Dr. Cullen is of opinion, that the leſs purgative preparations of mercury are beſt adapted to this purpoſe; accordingly he recommends a ſolution of corroſive ſublimate or oxymuriate of mercury, as the moſt proper, becauſe it is the moſt diuretic.

Wagner recommends the powder of ſquills, given with nitre, in hydropical ſwellings, and in a nephritis, and mentions ſeveral examples of cures which he performed, by giving patients from four to ten grains, with a double quantity of nitre.

When ſquill has been employed as a diuretic, it has been uſual to give it in powder, becauſe in this ſtate it is leſs apt to produce nauſea; and it has been cuſtomary to add neutral ſalts, as nitre, or cryſtals of tartar, eſpecially if the patient complained of much thirſt; others recommend calomel: and with a view to render the ſquills leſs offenſive to the ſtomach, it has been uſual to conjoin an aromatic.

In aſthmatic affections, or dyſpnœa, occaſioned by the lodgment of tenacious phlegm oppreſſing the lungs, or when the primæ viæ abound with mucous matter, it has been the expectorant uſually employed; and held in general eſtimation. As an expectorant, the ſquill may be ſuppoſed not only to attenuate the mucus, and thus facilitate its ejection, but by ſtimulating the excretory organ and mucous follicles, to excite a more copious excretion of it from the lungs, and thereby leſſen the congeſtion, upon which the difficulty of reſpiration very generally depends. Hence, in all pulmonic affections, excepting only thoſe of actual or violent inflammation, ulcer, and ſpaſm, the ſquill has been found to be a very uſeful medicine.

The root of ſquill is to the taſte very nauſeous, intenſely bitter and acrimonious; but without any perceptible ſmell: much handled, it exulcerates the ſkin. It is rendered more uſeful as an expectorant, when combined with nitrate of potaſs, tartarized antimony, or ipecacuanha; and in aſthma and dyſpnœa without fever, ſquill combined with ammoniacum is perhaps the beſt remedy we can employ.

Dr. Heſs ſays, he has cured the aſthma with the powder of ſquills. The efficacy of this powder, from four to twelve grains, in curing the aſthma, is atteſted by ſeveral. Med. Eſſ. Edinb. Com. Norimb. 1737, and 1739.

As an emetic, ſquill is very uncertain in its effect, producing in ſome perſons the moſt cruel vomiting, and in others exciting no nauſea in the largeſt doſes: nevertheleſs, when it readily and moderately induces vomiting, it proves more uſeful in hooping-cough and croup, than any other emetic.

For producing expectorant and diuretic effects moſt effectually, ſquill muſt be given in ſubſtance; but to excite vomiting, its infuſion in vinegar, or the oxymel, is more uſually employed. Of the dried ſquill, gr. j, in the form of a pill, may be given at firſt for a doſe, morning and evening, or every ſix hours; and the quantity gradually increaſed to grs. v or grs. vj, or till ſome degree of nauſea is induced, and its expectorant or diuretic operation obtained.

The officinal preparations of ſquills are the following: *viz. acetum ſcillæ*, *oxymel ſcillæ*, *pilulæ ſcillæ comp.*, *pulvis ſcillæ*, *ſyrupus ſcillæ maritimæ*, and *tinctura ſcillæ*. The “acetum ſcillæ,” or vinegar of ſquill, of the Lond. Ph. is prepared by macerating 1lb. of freſh ſquill root (bulb) dried in ſix pints of acetic acid, in a covered veſſel, for 24 hours; then expreſſing the liquor, and ſetting it aſide, that the feculencies may ſubſide; and laſtly, adding half a pint of proof-ſpirit to the clear liquor.

The “acetum ſcillæ maritimæ,” or vinegar of ſquill, of the Edinb. Ph. is prepared by macerating 2 oz. of the ſquill root (bulb) dried, with 2½ lbs. of diſtilled vinegar, for ſeven days; then expreſſing the liquor, and adding to it 3 oz. of alcohol; and when the feculencies have ſubſided, pouring off the clear fluids.

The "acetum ſcillæ," or vinegar of ſquill, of the Dub. Ph. is obtained by digeſting half a pound of freſh ſquill root (bulb) dried, with three pints of wine vinegar, for four days in a glaſs veſſel, with frequent agitation; then expreſſing the vinegar; and, after the feculencies have ſubſided, adding to it four fluid-ounces of rectified ſpirit.

This has been long uſed as an expectorant and diuretic in chronic catarrh, humoral aſthma, and dropſies. The doſe is from fʒſs to fʒij, given in cinnamon or mint-water. In large doſes it produces vomiting, and is occaſionally uſed as an emetic in the above-mentioned diſeaſes, when the ſtomach is loaded. For the "oxymel of ſquill," ſee OXYMEL *Scillæ*. For the "pills of ſquill," ſee PILLS.

The "pulvis ſcillæ," or powder of ſquill, of the Dub. Ph. is prepared by freeing ſquill roots (bulbs) from their membranous integuments, and cutting them in tranſverſe ſlices, then drying them upon a ſieve with a low degree of heat; and afterwards reducing them to powder, which muſt be preſerved in well-ſtopped glaſs phials.

The "ſyrupus ſcillæ maritimæ," or ſyrup of ſquill, of the Edinb. Ph. is formed of 2lbs. of vinegar of ſquill and 3½lbs. of refined ſugar powdered; diſſolving the ſugar by a gentle heat, ſo as to make a ſyrup. This ſyrup has the ſame properties, and is uſed for the ſame purpoſes, as the oxymel of ſquill. The doſe is from fʒj to fʒij, given in any aromatic diſtilled water.

The "tincture of ſquills" of the Lond. and Dub. Ph. is prepared by macerating 4oz. of recent ſquill root (bulb) dried, with two pints of proof-ſpirit, for 14 days, and filtering. The Dub. Ph. directs digeſtion for ſeven days, ſetting it aſide until the dregs are ſubſided, and pouring off the clear liquor. The doſe is from ♏ x to ♏ xxx, given in almond mixture, ammoniac mixture, or mucilage. Lewis. Woodville. Thomſon.

SQUILLS, *Wine of*, is an infuſion of the roots of ſquills in white wine for forty days, after which the ſquills are taken out, and the liquor preſerved for uſe. It is a gentle emetic, and is good againſt defluxions of rheum.

SQUILL, *White*, *Leſſer*, in *Botany*, a ſpecies of *pancratium*; which ſee.

SQUILL, *Squilla*, in *Natural Hiſtory*, a large claſs of animals, comprehending the ſhrimp, or *cancer crangon*; the crawfiſh, or *cancer fluviatilis*, or *cancer aſtacus* of Linnæus; the crab, or *cancer*; lobſter, or *cancer gammarus*; prawn, or *cancer ſquilla*. The *ſquilla* is alſo a genus deſcribed under CANCER: all which, according to Dr. Hill, make only one genus of inſects of the podaria kind. They properly belong to the genus of CANCER, under which they are deſcribed.

SQUILLA, in *Botany* and *Gardening*. See SCILLA.

SQUILLA *Aquæ Dulcis*, or *freſh-water ſhrimp*. Few perſons are aware of the damage done by the freſh-water ſhrimp among the ſmall fry of fiſh. This inſect is commonly very plentiful in ſtanding waters, and particularly in breeding-ponds, where they always have their prey in plenty before them; and often ſuffer none, or ſcarcely any of the numerous young fry hatched from the ſpawn of carp and tench, to live to grow up. They may be obſerved following the ſhoals of the young fry, and ſeizing multitudes one after another; and at other times lurking among the weeds to ſeize ſuch as ſtraggle by themſelves. If one of theſe inſects be put into a baſin of water with a dozen or two of theſe young fiſh, though as big as itſelf, it will very ſoon deſtroy them all. They kill numbers that they cannot eat, but leave them to rot.

SQUILLACE, in *Geography*, a ſea-port town of Naples, in Calabria Ultra, built on the verge of a rocky mountain, ſloping to the eaſt, about three miles from the ſea; and giving name to a gulf of the Mediterranean. It is the ſee of a biſhop, ſuffragan of Reggio, and contains eleven pariſhes and ſix convents. Virgil, for reaſons unknown, gave this city the epithet of "Navifragum," breaker of ſhips, as there are no hidden or apparent dangers attending the approach of veſſels; and we cannot ſuppoſe, that this correct poet ſhould be ſo negligent, as to confound the capacious bay of "Scyllacæum," as this is called, with the narrow paſs of Scylla in the Faro of Meſſina. In forming the body of Grecian commonwealths on the Italian ſhores, Athens furniſhed emigrants for Scyllacæum; but this ſettlement never made any figure in the confederacy. Rome ſent a colony hither. In the year 982 the emperor Otho II. was defeated under its walls by the forces of the Greeks. Montfort obtained this lordſhip in fee from Charles of Anjou; but in the next reign it was given to the Marſans. When this powerful houſe was overturned by the Aragoneſe, the fief was beſtowed upon that of Borgia, and was afterwards veſted in the marquis Gregori, who, from being a commiſſioner of the victualling office at Meſſina, roſe to be prime miniſter of Naples, and afterwards of Spain. Squillace prides itſelf on having given birth to Caſſiodorus, a ſtateſman of great abilities, and, conſidering the times he lived in, a very reſpectable author, beloved and honoured by Theodoric, and other Gothic monarchs. To this town, which was the place of his nativity, he retreated in his old age; and he amply deſcribes it; 33 miles S.S.E. of Coſenza. N. lat. 38° 48′. E. long. 16° 44′.

SQUINANCY, or ESQUINANCY. See QUINZY.

SQUINDER, in *Rural Economy*, a word ſignifying to burn inwardly, or in a ſmothering manner, as charcoal and ſome other ſubſtances are burnt.

SQUINTING, in *Medicine*, *Strabiſmus*, an irregular poſition and motion of the eyes, in which their axes do not converge to the object looked at.

It is certain, that when the axes of the eyes of perſons who do not ſquint are directed in different lines, objects are ſeen double; ſquinting perſons, however, do not ſee objects double. Yet it is well known that the principal reaſon which has been adduced for the ſingular phenomenon, that the images impreſſed upon the two eyes excite only one image in the mind, is, that the two images fall upon correſponding points of the eyes. The probability, therefore, is, that, in a ſquinting perſon, both eyes do not ſee the object looked at. In many caſes, indeed, "this is pretty evident to a by-ſtander," as ſir E. Home has remarked, "who is able to determine, that the direction of one of the eyes differs ſo much from that of the other, that it is impoſſible for the rays of light from any object to fall on the retinas of both; and therefore that one eye does not ſee the object. The ſame thing may be proved in another way. For ſince a ſmall deviation in the direction of either eye from the axis of viſion produces double viſion, any greater deviation muſt have the ſame effect, only increaſing the diſtance between the two images, till it becomes ſo great, that one eye only is directed to the object. In ſquinting there is evidently a greater deviation from the axis of viſion than in double viſion, and the object does not appear double: it is therefore not ſeen by both eyes." (See Phil. Tranſ. vol. lxxxvii. for the year 1797, p. 13.) It is manifeſt, indeed, that the perception is not diſtinct; but this, as Dr. Porterfield remarked, may be the reſult of habit and experience, by which the mind learns to correct the impreſſions of the ſenſes. (See Edin. Medical Eſſays, vol. iii. § 12.) In order to aſcertain the nature of this affection, it will be neceſſary to inveſtigate its varieties and cauſes.

Dr. Cullen was of opinion, that all the varieties of ſtrabiſmus, deſcribed by Sauvages and others, might be included under three ſpecies, which he deſignated by the appellations *habitualis*, *commodus*, and *neceſſarius*. The *firſt* of theſe may ariſe from the *habit* of uſing only one eye in viewing objects, while there is no defect either in the organ itſelf, or in the muſcles which move it. In this way children may learn to ſquint from having objects, which attract their attention, placed obliquely near the cradle; in which caſe it will be more eaſy to view them with the oppoſite eye alone, than to direct both towards the ſame point, and they will thus acquire the habit of neglecting the uſe and motions of the other eye. In a later period of life, the power of ſquinting voluntarily appears to be acquired by ſome by this practice of uſing one eye. Thus perſons who look much through teleſcopes, and of courſe employ one eye almoſt excluſively, may acquire the power of moving the one more than the other, or loſe a part of their command over the muſcles of the neglected eye.

Dr. Darwin mentions a ſingular caſe of ſquinting, in which the patient was equally expert in the uſe of either eye, but viewed every object preſented to him with only one eye at a time, and always with the eye on the ſide oppoſite the object. Thus, if the object was preſented on his right ſide, he viewed it with his left eye; and when it was preſented on his left ſide, he viewed it with his right eye. At the ſame time, Dr. Darwin found that he turned the pupil of that eye which was on the ſame ſide with the object in ſuch a direction, that the image of the object might fall on that part of the bottom of the eye where the optic nerve enters it, and where it would of courſe excite no impreſſion; and this inſenſible portion of the retina, Dr. Darwin aſcertained by ſome ingenious experiments to be four times greater in this patient than in ordinary perſons. When an object was held directly before this patient, he turned his head a little to one ſide, and obſerved it with but one eye, *viz.* with that moſt diſtant from the object, turning away the other in the manner juſt mentioned; and when he became tired with examining it with that eye, he turned his head the contrary way, and obſerved it with the other eye alone, with equal facility; but never turned the axes of both eyes on it at the ſame time. Phil. Tranſ. vol. lxviii. p. 86.

The *ſecond* ſpecies of ſquinting, however, which Dr. Cullen ſtyles *commodus*, and which is the effect of ſome imperfection in one of the eyes, is the moſt common form of the diſeaſe. It has generally been admitted, or aſcertained by experiment, in thoſe who have a confirmed ſquint of this nature, that one of the eyes is too imperfect to ſee diſtinctly. Of this, however, the patient is not always conſcious, as was evinced in a young lady, whoſe caſe is related by ſir Everard Home. Neither herſelf nor her friends believed that any defect of the eye exiſted; and upon being aſked if ſhe ſaw objects diſtinctly with both eyes, ſhe ſaid certainly, but that one was ſtronger than the other. To aſcertain the truth of this, he covered the ſtrong eye, and gave her a book to read, when, to her aſtoniſhment, ſhe found ſhe could not diſtinguiſh a letter, or any other near object. More diſtant objects ſhe could ſee, but not diſtinctly: when ſhe looked at a bunch of ſmall keys in the door of a book-caſe, about twelve feet from her, ſhe could ſee the bunch of keys, but could not tell how many there were.

The obſcurity of viſion in one eye, then, is the cauſe of this common ſpecies of ſquinting, and may occaſion this irregularity in the following way. The obſcure image, being ſo imperfectly formed in the weak eye, as to excite little attention in the mind, the uſe of the eye, and its uniform direction to the ſame object with the other, may have been neglected from the beginning; for as diſtinct viſion was obtained at once by the perfect eye, the end was anſwered, and therefore there was no neceſſity for any exertion to employ the other. Or on the other hand, in the effort to get rid of the confuſed image, the muſcles may have acquired an irregular and unnatural action. It is remarked by ſir E. Home, that the direction, which the eye takes under either of theſe circumſtances, is inwards, towards the noſe; becauſe the *adductor* muſcle is ſtronger, ſhorter, and its courſe more in a ſtraight line, than any of the other muſcles of the eye. Phil. Tranſ.

In the *third* ſpecies, or ſtrabiſmus *neceſſarius* of Cullen, the ſquinting is the reſult of ſome peculiarity or change in the form or ſituation of the eye or its parts; whence a perfect and diſtinct image of any object can only be obtained by an oblique direction of the axis of the eye. Dr. Porterfield has pointed out two varieties of this kind, ariſing, the one from an oblique poſition of the cryſtalline lens within the eye, by which the image of an external object is refracted out of the line of the axis of the eye;—and the other, from an oblique poſition and greater protuberancy of the cornea, which produces a ſimilar effect. (See Edin. Medical Eſſays, vol. iii. art. 12.) Theſe appear to be ſynonimous with the ſtrabiſmus *à cryſtallino*, and *S. myopum* of Sauvages (Noſol. Meth. claſs iv. gen. i. ſpec. 12 & 9.) Other partial diſeaſes of the eye may contribute to render oblique viſion the moſt convenient; ſuch as *leucoma*, *hypopion*, *pterygium*, &c. enumerated by Sauvages as conſtituting his eleventh ſpecies, *S. caligantium*.

Cure of Squinting.—The two firſt ſpecies of ſquinting, ariſing from the habit of uſing one eye only, or from the weakneſs or imperfection of the other, may be ſometimes cured. The third, which ariſes from ſome malformation of the eye or its parts, is ſcarcely remediable.

The principle of cure in the two firſt ſpecies is nearly the ſame; namely, the conſtant exerciſe of the neglected eye, whether naturally weak or not. This may be effected by covering the ſtrong eye, or that which is always employed, and confining the perſon to the uſe of the neglected or weak eye. For in this way, the muſcles of the latter, from conſtant action, will become perfect in the habit of directing the eye upon the object, gain ſtrength in that action, and acquire a power of adjuſting the eye. When this is eſtabliſhed in a ſufficient degree, the other eye may be ſet at liberty. The time that will be neceſſary for the cure, will depend upon the inveteracy of the habit, the length of time that the muſcles have been left to themſelves, and the degree of weakneſs of the ſight: for it is with difficulty that muſcles acquire an increaſed degree of action after having been long habituated to a more limited contraction. Dr. Darwin obſerves, that if the ſquinting has not been confirmed by long habit, and one eye be not much worſe than the other, a piece of gauze ſtretched on a circle of whalebone, to cover the beſt eye in ſuch a manner as to reduce the diſtinctneſs of viſion of this eye to a ſimilar degree of imperfection with the other, ſhould be worn ſome hours every day.

For the cure of the curious caſe related by the ſame ingenious phyſician, in which there was no defect in either eye, but merely a depraved habit of uſing both eyes ſeparately, Dr. Darwin ſays, "a gnomon of thin braſs was made to ſtand over his noſe, with a half circle of the ſame metal to go round his temples; theſe were covered with black ſilk, and by means of a buckle behind his head, and a croſs-piece over the crown of his head, this gnomon was managed ſo as to be worn without any inconvenience, and projected before his noſe about two inches and a half. By the uſe of this gnomon he ſoon found it leſs inconvenient to view all objects with the eye next to them, inſtead of the eye oppoſite to them.

"After this habit was weakened by a week's uſe of the gnomon, two bits of wood, about the ſize of a gooſe-quill, were blackened all but a quarter of an inch at their ſummits: theſe were preſented for him to look at, one being held on one ſide the extremity of his black gnomon, and the other on the other ſide of it. As he viewed theſe, they were gradually brought forwards beyond the gnomon, and then one was concealed behind the other. By theſe means, in another week, he could bend both his eyes on the ſame object for half a minute together.

"By the practice of this exerciſe before a glaſs, almoſt every hour in the day, he became in another week able to read for a minute together with his eyes both directed on the ſame objects; and I have no doubt, if he has patience enough to perſevere in theſe efforts, but he will in the courſe of ſome months overcome this unſightly habit." Phil. Tranſ. vol. lxviii. p. 89.

Philoſophers, as well as phyſicians, have adopted various hypotheſes, in order to account for this defect in viſion. It has been generally ſuppoſed to proceed, according to the preceding ſtatement, from the want of a due correſpondence in the muſcles of the eyes, which not acting in a proper concert with one another, are not able to point both eyes at one object. M. de la Hire apprehended, that this diſorder proceeded from a defect in the eye itſelf having the moſt ſenſible part of the retina not placed in the axis of the eye, but at ſome diſtance from it on one ſide or the other; and that, therefore, not the axis, but this more ſenſible part of the retina is turned towards the object on which the axis of the other eye is fixed, ſo that both axes are not directed to the ſame point.

He ſuppoſed ſquinting, alſo, ſometimes to be owing to the oblique ſituation of the cryſtalline humour in one of the eyes. Theſe hypotheſes are examined and refuted by Dr. Jurin, who, in order to account for this defect, conſiders the diſpoſition and ſituation of the eyes in a ſound ſtate. When we look directly forwards at a diſtant object, the pupil of each eye lies in the middle of the aperture formed by the eye-lids; ſo that the diſtance between the two pupils conſiſts of the breadth of the noſe and half the breadth of the aperture of each eye; and this diſtance between them is always preſerved, however obliquely we turn our eyes. In looking at near objects, the diſtance between the pupils is ſomewhat leſs, but ſtill it is always the ſame in all oblique directions of the eyes, as well as when we look ſtraight forwards; by which means the axes of both eyes are directed forwards to the ſame point, in both theſe caſes of looking at diſtant and near objects. But in thoſe who ſquint, when the pupil of the undiſtorted eye is ſeated in the middle of the aperture, as in looking directly forwards, the pupil of the other eye is drawn cloſe to the noſe, and conſequently, the diſtance between the two pupils is conſiderably leſs than in other perſons; and this leſs diſtance continues the ſame in all oblique directions for the eyes; ſo that two axes are never pointed at the ſame object, though the muſcles do ſo far act in concert with each other, as to move both eyes the ſame way at the ſame inſtant of time.

This vicious habit, Dr. Jurin obſerves, may eaſily be contracted by a child, if he is often laid into his cradle in ſuch a poſition as to be able to ſee either the light, or any other remarkable object, with one eye only: and when by this means he is brought to ſquint, and the habit is confirmed, he apprehends it will be in vain to attempt a cure by his wearing tubes, or ſhells, with ſmall holes to look through; for, notwithſtanding every help of this kind, he will continue to ſee through them diſtinctly with one eye only, and will ſtill diſtort the other. The true method of cure he takes to be the following: when the child is arrived at ſuch an age as to be capable of obſerving directions, place him, ſays he, directly before you, and let him cloſe the undiſtorted eye, and look at you with the other. When you find the axis of this eye fixed directly upon you, bid him endeavour to keep it in that ſituation, and open his other eye. You will now ſee the diſtorted eye turn away from you towards his noſe, and the axis of the other eye will be pointed towards you. But with patience and repeated trials, he will, by degrees, be able to keep his diſtorted eye fixed upon you, at leaſt for ſome little time, after the other is opened; and when you have brought him to keep the axes of both eyes fixed upon you, as you ſtand directly before him, it will be time to change his poſture, and to ſet him firſt a little on one ſide of you, and then to the other, and ſo to practiſe the ſame thing; and when in all theſe ſituations he can perfectly and readily turn the axes of both eyes towards you, the cure is effected. An adult perſon, he ſays, may practiſe all this by a glaſs, without a director, though not ſo eaſily as with one; but the older he is, the more patience will be neceſſary. Smith's Optics, Rem. p. 30.

M. Buffon infers, from a great number of obſervations, that the true and original cauſe of ſquinting is an inequality in the goodneſs, or in the limits of diſtinct viſion in the two eyes. When one of the eyes, he ſays, is much weaker than the other, we do not direct it towards the object, but make uſe of the ſtronger eye only: when the eyes are equally good, we ſee more diſtinctly with both eyes than with one, by about a thirteenth part; but when they are unequal in goodneſs, objects appear leſs diſtinct with both eyes than with one. It is no wonder, therefore, that perſons, ſubject to this inequality, chuſe to make uſe of one eye, and turn the other aſide. This inequality in the goodneſs of the eyes is the general cauſe of ſquinting, according to M. Buffon; and others, with reſpect to this, are accidental. All the perſons whom he examined, if they ſquinted at all, did ſo from this cauſe; and this effect is ſo neceſſary, that, he ſays, it is not poſſible to cure a perſon of ſquinting, whoſe eyes differ much in point of goodneſs, except, perhaps, by firſt bringing them nearer to an equality by means of glaſſes. To the ſame purpoſe Dr. Reid obſerves, that, having examined above twenty perſons who ſquinted, he found in all of them a defect in the ſight of one eye. And this writer is of opinion, that the centres of the two eyes of ſquinting perſons correſpond with them as with others, ſo that if they could be brought to the habit of directing their eyes aright to an object, they would not only remove a deformity, but likewiſe improve their ſight.

In examining the limits of diſtinct viſion in ſeveral children who did not ſquint, M. Buffon found, (contrary to Dr. Jurin's obſervation,) that they did not ſee by any means either ſo far off, or ſo near as adult perſons; ſo that, as we advance in age, the limits of diſtinct viſion are extended both ways; and this, he ſays, is one reaſon why children ſquint more than adult perſons.

When the eyes of thoſe perſons who ſquint do not differ much in point of goodneſs, M. Buffon thought that the moſt ſimple, the moſt natural, and the moſt effectual method of curing it, would be to cover the good eye for ſome time; for the diſtorted eye would thus be obliged to act and turn itſelf directly towards objects, and, by degrees, this would become natural to it.

The reaſon why thoſe perſons who ſquint generally turn the weak eye towards the noſe, he ſays, is, that in that ſituation, the direction of its axis is as diſtant as poſſible from that of the good eye: and beſides, in this place, the noſe conceals many objects from its view, ſo that this ſituation is the leaſt diſadvantageous to it of any other.

In ſome caſes, M. Buffon obſerves, that the eyes have what is commonly called a *caſt* only, in conſequence of the optic angle being too great or too ſmall, when they are of equal goodneſs. This, he ſays, is generally the reſult of habit, acquired very early, in conſequence of the miſmanagement of children, and that it is often eaſily cured. If the eye that ſquints be turned towards the temples, he ſays, he has generally found that there is no great inequality in the goodneſs of the two; and that, in this caſe, the cauſe being only a vicious habit, the cure has been completed by covering the good eye for a fortnight only. In order to judge with any certainty of the inequality of goodneſs in the two eyes, and the poſſibility of the cure of ſquinting, it is neceſſary, he ſays, to cover the good eye for ſome time, in order to exerciſe the bad eye, and give it an opportunity of gaining ſtrength, after which it will be more eaſy to judge whether the cure be poſſible or not. Acad. Par. 1743, p. 329. 342. Reid's Inq. into the Human Mind, p. 253—257. See *Phyſiology of the* Eye.

SQUINZANO, in *Geography*, a town of Naples, in the province of Otranto; 6 miles N.W. of Lecce.

SQUIRE, Samuel, in *Biography*, a learned Engliſh prelate, was born at Warminſter in 1714. He was educated at St. John's college, Cambridge, of which he became a fellow. After various inſtances of preferment, he obtained the vicarage of Greenwich, and was appointed clerk of the cloſet to the prince of Wales, his preſent majeſty. In 1760 he was promoted to the deanery of Briſtol; and in the following year he was advanced to the ſee of St. David's. He died in 1766, leaving behind him ſeveral works of reputation, beſides a number of ſingle ſermons. His principal pieces are as follow. In his profeſſion as a divine, he wrote "The ancient Hiſtory of the Hebrews vindicated;" "Indifference for Religion inexcuſable;" and "The Principles of Religion made eaſy to young Perſons." In claſſical literature, he publiſhed "Two Eſſays: (1) A Defence of the ancient Greek Chronology; (2) An Inquiry into the Origin of the Greek Language;" and an edition of "Plutarch de Iſide et Oſiride," Gr. and Engl., with commentaries and various readings. His works, as a political writer, are, "An Inquiry into the Nature of the Engliſh Conſtitution, or an hiſtorical Eſſay on the Anglo-Saxon Government both in Germany and England;" "An Eſſay on the Balance of Civil Power in England;" and "Remarks upon Mr. Carte's Specimen of the General Hiſtory of England." He left in MS. a Saxon grammar, compiled by himſelf. Dr. Squire was a fellow of the Royal and Antiquarian Societies. Gen. Biog.

SQUIRREL, Sciurus, formed of *σκια*, *ſhade*, and *ȣρα*, *tail*, becauſe the tail ſerves this animal for an umbrella, is a genus of animals deſcribed under Sciurus.

There is great diverſion in hunting the common Engliſh ſquirrel, and its fleſh is very delicate and well taſted. The only ſeaſon for hunting it is in autumn, and the beginning of winter, at which time the creature is fat; and the leaves being off the trees, it may be ſeen as it leaps from bough to bough, which, when purſued, it does with ſurpriſing agility.

In the ſummer they build their neſts, which the ſportſmen call *drays*, very artificially in the tops of trees, with ſticks, moſs, and ſuch other things as the woods afford: to their neſt they have two holes, and they ſtop up that on the ſide the wind blows, as Pliny has remarked; they fill this lodging, during the ſeaſon, with nuts and other fruits, which are to ſerve them in the ſevere weather, when the trees afford nothing. They ſleep in the midſt of this proviſion a great part of the winter, and that ſo ſoundly, that they will not be waked by ever ſo loud a noiſe made juſt under their drays; though at other times they fly out immediately on hearing any noiſe, even at a conſiderable diſtance.

In the ſpring the female is ſeen purſued from tree to tree by the males, feigning an eſcape from their embraces.

The tail of the ſquirrel, which is as large as the body, though compoſed almoſt entirely of hair, ſerves the creature in ſome ſort inſtead of wings; for by means of it the body is kept ſuſpended in the air, without any viſible ſinking, while the creature throws itſelf from the boughs of one tree to thoſe of another of equal height. But the more general leaps the ſquirrel takes, are from the outermoſt branches of a high tree to another ſomewhat lower at a diſtance: it is wonderful to ſee how far it will be carried in theſe leaps; and if it miſſes the tree it aims at, and by that means falls from the top of ever ſo high a tree to the ground, the tail ſupports it ſo well that it comes ſoftly down, and receives no harm. The hunting of the ſquirrel is moſt agreeably performed in woods of a young growth, the trees of which may be ſhaken by the hands; and it is neceſſary to take out ſome means of diſlodging them from the clefts of trees, in which they will take refuge, and from which they will never be removed by mere noiſe.

Many people uſually go together on this expedition, and ſometimes they carry bows and arrows for the diſlodging of the prey from theſe places; ſometimes bludgeons, or ſhort or thick ſtaves, loaded at one end with lead, to prevent their lodging in the tree when they are thrown up. The ſquirrel, which in its fright has taken refuge in any part of a tree, and is not to be diſlodged either by hallooing or ſhaking the tree, will always quit the place as ſoon as an arrow or bludgeon has been well aimed at it, and will give a farther chace.

The ſquirrel is always fond of a large oak in time of danger, and runs to the neareſt it can find, as ſoon as it ſees itſelf purſued: in ſome part of the upper boughs of this tree it ſits ſecure from the men and dogs, and as it is too troubleſome to the ſportſmen to climb every tree, the only method is to ſhoot arrows, and throw bludgeons at it; it is very ſeldom hurt by theſe, unleſs hit juſt upon the head, for its back-bone is ſo ſtrong, that it will bear nearly as hard a blow as a dog, without danger of hurt. So long as the ſtrength and ſpirits of the creature laſt, it always keeps in the tops of the higheſt trees; but when it grows weary, it comes down, and takes ſhelter in the hedges. The ſquirrel then ſoon becomes a prey to the dogs, or is very often killed upon the ground, in attempting to gain the hedge in places where there is no continued chain of trees by which it can come at it.

It is obſerved, that the gullet of this animal is very narrow, to prevent it from diſgorging its food in deſcending of trees, or in its leaps downwards.

SQUIRTING or Spurting *Cucumber*, in *Gardening*, the common name of a wild ſort of cucumber, which is ſometimes cultivated in gardens for the ſake of curioſity, and for the peculiar property which it poſſeſſes of inſtantly burſting the capſules of the ripe fruit, on being touched, with much elaſticity and violence, ſo as to throw the juice and ſeeds which they contain forcibly to a great diſtance all around, to the great ſurprize of thoſe who may have touched them. See MOMORDICA.

It likewiſe affords the medicinal ſubſtance known by the name of *elaterium*.

SQUIRZINA, in *Geography*, a town of the duchy of Warſaw; 50 miles W.N.W. of Poſen.

SRADHA, the name of a ceremony among the Hindoos, of a very intereſting and affecting nature; being obſequies in honour of departed anceſtors.

The Hindoo Pantheon furniſhes ſome particulars explanatory of this intereſting and affecting ceremony, which, the author tells us, is an oblation of daily recurrence with Brahmans and rigid Hindoos who can afford it. It is offered not only in honour of deceaſed anceſtors, but for their comfort; as the manes, as well as the gods connected with them, enjoy, like the gods of the Greeks, the incenſe of ſuch offerings; which are farther of an expiatory nature, ſimilar, it may be preſumed, in their efficacy, as well as in the motives that induce them, to the maſſes of the Romiſh church. Over theſe ceremonies of Sradha, Yama preſides, in his character of Sradhadeva, or lord of the obſequies. See SRADHADEVA and YAMA.

Mr. Colebrooke tells us (Aſ. Reſ. vol. vii.), that the prieſts, in the performance of the Sradha, meditate the gayatri, and thrice repeat "Salutation to the gods, to the manes of anceſtors, and to mighty ſaints; to Swaha (goddeſs of fire); to Swadha (the food of the manes); ſalutation to them for ever and ever." Of the gayatri, &c. of this quotation, ſee O'M, SWADHA, and SWAHA.

M. le Gentil found a ſtrong reſemblance between the funeral rites of the Chineſe and the Sradha of the Hindoos. On which ſir William Jones (Aſ. Reſ. vol. ii.) ſays, "that all the circumſtances which have been mentioned, under the two heads of literature and religion, ſeem collectively to prove, (as far as ſuch queſtion will admit of proof,) that the Chineſe and Hindoos were the ſame people; but having been ſeparated near four thouſand years, have retained few ſtrong features of their ancient conſanguinity; eſpecially as the Hindoos have preſerved their old language and ritual, while the Chineſe very ſoon loſt both. And the Hindoos have conſtantly intermarried among themſelves; while the Chineſe, by a mixture of Tartarian blood from the time of their firſt eſtabliſhment, have at length formed a race diſtinct in appearance from both Indians and Tartars."

In the third chapter of the Inſtitutes of Menu, the rules for the performance of the Sradha are detailed with prolixity. Among other particulars of the moſt important of thoſe ceremonies, we learn that Brahmans only ought to be invited to the feaſt, which forms one important rite; and ſuch Brahmans ſhould be of holy and learned habits. A Sudra, that is, one of the fourth or ſervile claſs, is urgently prohibited as a gueſt. Let the houſekeeper, it is ſaid, who knows his duty, perform each day a Sradha with boiled rice, and the like, or with water, or with milk, roots, and fruit; for thus he obtains favour from departed progenitors, &c. &c. &c.

The following extract is taken from Colebrooke's Diſſertation on the religious Ceremonies of the Hindoos, in the ſeventh volume of the Aſiatic Reſearches; which article contains much valuable matter, and many curious particulars of the Sradha, or feaſt attending funeral obſequies.

"A dying man, when no hopes of his ſurviving remain, ſhould be laid on a bed of Kuſa graſs (ſee KUSA), in the open air, his head ſprinkled with water drawn from the Ganges, and ſmeared with clay brought from the ſame river. A Salagrama ſtone (ſee SALAGRAMA) ſhould be placed near him, holy ſtrains from the Veda (ſee VEDA) ſhould be chaunted aloud, and leaves of holy baſil ſcattered over his head.

"When he expires, the corpſe muſt be waſhed, perfumed, and decked with wreaths of flowers, and carried by the neareſt relations to ſome ſpot in the foreſt, or near water: the funeral pile is lighted from the conſecrated fire maintained by the deceaſed. (See of this under our articles SAGNIKA and SAMI.) The neareſt relation applies the flaming brand to the pile, hung round with flowers; and the attendant prieſts recite the appropriate invocations: 'Fire! thou waſt lighted by him; may he, therefore, be reproduced from thee, that he may attain the regions of celeſtial bliſs. May this offering be auſpicious!' All who followed the corpſe walk round the pile, but may not view the fire. They then proceed to the river, and, after bathing, preſent oblations of water to the manes of the deceaſed, ſaying, 'May this oblation reach thee!' Elegiac verſes, ſuch as the following, are then recited.

"1. Fooliſh is he who ſeeks for permanence in the human ſtate; inſolid, like the ſtem of the plantain-tree; tranſient, like the foam of the ocean.

"2. When a body, formed of five elements, to receive the reward of deeds done in its own former perſon, reverts to its own five original principles, what room is there for regret?

"3. The earth is periſhable; the ocean, the gods themſelves paſs away: how ſhould not that bubble, mortal man, meet deſtruction?

"4. All that is low muſt finally periſh; all that is elevated muſt ultimately fall; all compounded bodies muſt end in diſſolution; and life be concluded by death."

Excluſive of the daily Sradhas, or feaſts, given by wealthy individuals, formal obſequies are performed ninety-ſix hours in every year, on particular days. "It ſhould be obſerved," Mr. Colebrooke tells us, reſpecting the practice of giving food at theſe obſequies, "that Brahmans generally give it to one or more of their own relations. A ſtranger, unleſs indigent, would be very unwilling to accept the food, or attend at a Sradha, for the purpoſe of eating it. The uſe of fleſh meat is poſitively enjoined to Hindoos at certain obſequies, and recommended at all. (See Inſt. of Menu, c. iii. v. 124. 268, &c.) But the precepts of their lawgivers are, by ſome, deemed obſolete in the preſent age; and are evaded by others, who acknowledge the cogency of theſe laws. Theſe commonly make a vow of abſtaining from fleſh meat, and conſider that vow as more binding than the precepts here alluded to. Others, again, not only eat meat at obſequies and ſolemn ſacrifices, but make it their common diet, in direct breach of their religion." It hence appears clear, that the idea ſo common in Europe, of the univerſal abſtinence of Hindoos from fleſh meat, is as erroneous as general. Some pages of the Hindoo Pantheon are devoted to prove this fact; and it is fully proved, that not only all Hindoos may, but that a great majority of thoſe who can obtain it, including Brahmans themſelves, actually do, eat meat.

The feaſt attendant on the ceremonies of the Sradha can be given only by the ſon, or grandſon, or male iſſue of the defunct; and as the greateſt importance is attached by Brahmans and others to the due performance of theſe ceremonies, default of male iſſue is deprecated as among the heavieſt of misfortunes. The Hindoo books, therefore, abound in inſtances of the efficacy of prayers, ſacrifices, alms to Brahmans, pilgrimages, auſterities, &c. in obtaining this grand object of comfort to departed ſouls. “ Appeaſing the manes,” by the Sradha, is as common in the mind of a Hindoo, as relieving the pains of purgatory by maſſes is in that of a Papiſt. Though the ceremonies differ, the principle is ſtrikingly ſimilar. Being childleſs is felt as an angry viſitation of the gods, inflicted partly for ſins in a former ſtate of exiſtence: they are, therefore, propitiated by alms, pilgrimages, &c. One mode of removing ſterility is by circumambulating an image, or tree, ſacred to ſome deity. (Of this ſee under PRADAKSHNA, the name of this ceremony.) If every thing fail, there is, however, ſtill a remedy by adoption, accompanied by certain ceremonies, expenſive, according to the means of the party. Another is by giving daughters in marriage with like ceremonies; all of which are minutely detailed in the ritual. For all theſe proceedings divine authority can be quoted. Holy men, or even divinities, in the times of their terreſtrial ſojournments, are related to have done the like. “ He,” ſays Menu, “ who has no ſon, may appoint a daughter to raiſe up a ſon for him, ſaying, ‘ The male child who ſhall be born from her in wedlock ſhall be mine, for the purpoſe of performing my obſequies.’

“ In this manner Dakſha himſelf, lord of created beings, anciently appointed all his fifty daughters to raiſe up ſons to him, for the ſake of multiplying his race.”

SRADHADEVA, in *Hindoo Mythology*, a name given to the Pluto of their infernal regions. It means lord of the Sradha, a feaſt often, by many daily, offered in commemoration of deceaſed anceſtors. (See SRADHA.) The more common name for the lord of the obſequies is *Yama*; which ſee.

SRAMANA, a name of the Eaſtern deity *Boodh*; which ſee.

Sakya, Sravaka, and Sugata, (which ſee,) are others of his names. So is Gotama, or Godama. The union of the firſt and laſt of theſe names, a little altered in the pronunciation, produced that of Somonocodom, by which he is called by ſome writers. See GODAMA.

SRAVAKA, the name of the laity of the Jainas, a ſect of ſchiſmatic Hindoos. Their prieſts are called Yati. (See JAINA and YATI.) A name alſo of the god Budha, or *Boodh*; which ſee. For a notice of the religion and cuſtoms of the ſect of Sravaka, ſee Moor on Hindoo Infanticide, p. 174. Among the Mahrattas, the Sravakas are called Shevari.

SRBORNICK, in *Geography*, a town of Boſnia; 40 miles N.N.E. of Boſnaſerai.

SREDNEI, an iſland in the Frozen ocean, at the mouth of the Indigirda, about 40 miles in circumference, of a triangular form. N. lat. 72° 52′. E. long. 154° 155°.—Alſo, a town of Ruſſia, in the government of Tobolſk; 20 miles N.N.W. of Taſſievſkoi.

SRI, in *Hindoo Mythology*, is a name given to ſeveral goddeſſes; ofteneſt perhaps to Lakſhmi, the goddeſs of proſperity and abundance. This name is in the firſt caſe Sris, which ſir William Jones remarked as reſembling, both in name and character, the goddeſs of abundance of the Latins; and he ſays, that in very ancient temples near Gaya there are images of Lakſhmi, with full breaſts, and a cord twiſted under her arm, like a horn of plenty, which looks very much like the old Grecian and Roman figures of Ceres. (See LAKSHMI.) The word Sri, however, although given as a name or epithet to the Ceres of India, and to the other great goddeſſes Parvati and Saraſwati, is not confined to them: it means fortunate, happy, &c. as well as bleſſed or divine; and is ſometimes prefixed to the names both of gods and men.

SRI BHAGAVATA, the title of a work in the Sanſcrit language, of great celebrity among the Hindoos. It is uſual to aſcribe this work to Vyaſa, the reputed compiler or author of the Vedas, Puranas, Mahabarat, and other works. But the real author of the Sri Bhagavata is Vopadeva, who, in attempting to revive the leading doctrines of Vyaſa, opened a door to the reconciliation of the various ſects of Hindoos, numerouſly divided and ſubdivided as they are, and, as far as hiſtorical evidence can be traced, ever have been. We muſt refer the reader to our article SECTS *of Hindoos*, for farther information on theſe points. (See alſo VYASA.) Under our article PURANA we have given a ſuccinct account of the mythological romances ſo called, that are ſo highly venerated in India as inſpired poems. Of theſe the Sri Bhagavata is reckoned the eighteenth and laſt; and whatever differences of opinion may exiſt, and very wide differences do exiſt, as to the antiquity and form of the other Puranas, it ſeems a point generally agreed on, that the Bhagavata is much more modern than the reſt, and cannot, in its preſent form, claim an age of more than ſix hundred years.

The main ſubject of the Bhagavat is the life and actions of Kriſhna; including the extravagant and myſtical details of his incarnation, miracles, debaucheries, and various fooleries; intermixed, however, with ſublime effuſions of pure theology and morals. (See MYSTICAL *Poetry*.) Like moſt of the other reſpected writings of the Hindoos, it contains much to applaud and admire; but more, whether viewed philoſophically or morally, to reprehend. It is compriſed in twelve books, and, like the other poems bearing the common denomination of Purana, contains, beſides the general thread of ſectarial theology interwoven throughout, five ſubjects, *viz.* primary creation, or creation of matter in the abſtract; ſecondary creation, or the production of ſubordinate beings, both ſpiritual and material; chronological account of their grand periods of time called Manwantara; genealogical riſe of families, particularly of thoſe who have reigned in India; and, laſtly, a hiſtory of the lives of particular families.

This work is in general eſtimation, and is found in moſt of the vulgar dialects of India, and in the Perſian language. It has alſo appeared in a very imperfect and abridged form, in French, under the title of Bagavadam, tranſlated from the Tamul verſion. Its title is derivable from Bhagavan, one of the names of Kriſhna and Viſhnu; and Bhagavan from Bhaga, meaning, it is ſaid, the author of exiſtence, or lord of nature. (See SIVA.) Sri is a prefixture of reſpect, extenſively applied. (See SRI.) The modern ſect, who adhere to the liberal doctrine expounded in this work, are called Bhagavatas. But we muſt again refer to our article SECTS *of Hindoos*, for an explanation of the nature of the Hindoo ſectarial diſtinctions. See alſo KRISHNA, for an account of the hero of the Bhagavat.

SRIDEVI, in *Hindoo Mythology*, is a name given by ſeveral ſects to the goddeſs of their adoration; ſuch individual goddeſs being called the ſakti, or energy of her lord. In explanation of this, we refer to our article SAKTI. Sridevi means the bleſſed goddeſs, and is given to all the three great goddeſſes, Lakſhmi, Parvati, and Saraſwati.

Sridevi is likewiſe the name of the wife of Dakſha, who was Brahma in a human ſhape. In this character ſhe ſeems to be both the daughter and mother of Parvati. See PIKESWARI and SRADHA.

SRIMANA, a name of Kartikya, the Hindoo regent of the firmament. See KARTIKYA.

SRIMANT, an appellation of reſpect uſed in the third perſon to the Peſhwa, or chief perſon of the Mahratta empire. See PESHWA.

SRINAGUR, in *Geography*. See SIRINAGUR.

SRIPADA, a name, or word, uſed among the Hindoos, meaning a divine footſtep, for which ſuppoſed impreſſions they have a very reverential feeling. On the top of the lofty mountain on the iſland of Ceylon, which European geographers call Adam's peak, the Hindoos fancy there is a ſripad; and accordingly pilgrimages are made to it from diſtant parts of India. Viſhnu, it is ſaid, alighted on this ſpot, and left the holy and indelible impreſſion. In the neighbourhood of temples, or at their threſhold, it is not unuſual to ſee a flat ſtone emboſſed or engraved with the impreſſion of two feet, joined from heel to toe; ſuch being the attitude of adoration: and it is ſaid that ſuch ſtones are the laſt terrene ſubſtance preſſed by the feet of the unhappy victims of ſuperſtition, who burn themſelves alive on the pile of their huſbands. They ſtep from theſe flat ſtones upon the pile, and then appertain more to the next world than to this. The next ſtep is into the preſence of the gods; or, in the caſe of temples, to their holy place.

The Hindoos are not the only people who have a veneration for the myſtical impreſſions of feet. The ſripad above mentioned on Ceylon was ſaid by our early zealous miſſionaries to have been left by Adam; they endeavouring to eſtabliſh the fact of that choſen iſland having been the Eden of our firſt parents. (See LANKA.) In the holy land, miraculous ſripada, or footſteps, are ſtill ſhewn and reverenced, as left by the laſt preſſure of our Saviour on the earth. On this ſubject the reader will find ſome intereſting diſcuſſion in Dr. Clark's Travels, vol. ii. p. 584.

SRIRANGA, a name of the Hindoo god Siva. The name is Ranga, with the epithet Sri prefixed, meaning holy or bleſſed. (See RANGA, SIVA, and SRI.) Seringapatam, or Seringapatan, means the city of Sriranga, or of the holy Ranga.

SRIVIRUPAKSHA, a name of Siva, the deſtructive or transforming power of the Hindoo divine triad. Virupakſha is ſaid to mean with *three eyes*, Siva being ſo gifted; and hence named *Trilokan*; which ſee. (See alſo SIVA.) An eminent Sanſcrit ſcholar tranſlates the name Virupakſha, "with a diſagreeable countenance." The epithet Sri prefixed means bleſſed or divine. See SRI and VIRUPAKSHA.

Madame Dacier, in a note on the ninth book of the Iliad, has a paſſage applicable to the mythological ſubject of this article. The ancients, ſhe ſays, gave the name of Jupiter not only to the god of heaven, but likewiſe to the god of hell, as is ſeen here by the epithet of "infernal Jove," and to the god of the ſea, as appears from Eſchylus. They thereby meant to ſhew, that one ſole deity governed the world; and it was to teach the ſame truth, that the ancient ſtatuaries made ſtatues of Jupiter, which had three eyes. Priam had one of them in that manner in the court of his palace, which was there in Laomedon's time. After the taking of Troy, when the Greeks ſhared the booty, it fell to the lot of Sthenelus, who carried it into Greece.

Siva, the Indian Jove, is, in like manner, deemed variouſly the god of the three regions of the univerſe, as denoted by his three eyes, trident, &c. See PARVATI and TRISULA.

SRODA, or SVODA, in *Geography*, a town of the duchy of Warſaw; 14 miles S.E. of Poſen.

SRSEM, or STRIM, a town of the duchy of Warſaw; 20 miles S. of Poſen.

SRSERED. See SERAT.

SSE-TCHUEN, a town of Corea; 33 miles S.W. of Tſin-tcheou.

SSIDA, a town of Japan, in the iſland of Niphon; 18 miles S. of Fitaqua.

SSIERPSCH, a town of the duchy of Warſaw; 16 miles N. of Ploczk.

SSOKAL, a town of Auſtrian Poland, in the palatinate of Belz; 10 miles N.E. of Belz.

SSUUS, a town of Japan, on the N. coaſt of Niphon; 20 miles S.E. of Noto.

ST, an indeclinable term, chiefly uſed to command ſilence. The Romans had theſe two characters written over the doors of the eating-rooms, as who ſhould ſay, *ſed tace*, or *ſilentium tene*.

Porphyry obſerves, the ancients made a point of religion of it, not to ſpeak a ſingle word in paſſing in or out of the doors.

STAAL, *Madame de*, in *Biography*, an ingenious French writer, firſt known by the name of Mademoiſelle de Launay, was daughter of a painter at Paris. Her father being obliged to quit the kingdom, ſhe was left in a ſtate of poverty. She had enjoyed the advantages of a good education at a priory in Rouen; but her patroneſs dying, ſhe was under the neceſſity of engaging herſelf as bed-chamber woman to the ducheſs of Maine; who ſoon diſcovering the talents of her ſervant, employed her in all the theatrical entertainments which ſhe gave at her ſeat of Sceaux. For ſome of theſe De Launay wrote verſes, and for others ſhe formed the plans, and thus obtained the perfect and unlimited confidence of her miſtreſs, and the friendſhip of all the men of wit and letters who frequented that court. Following the fortunes of her miſtreſs, ſhe was involved in the diſgrace incurred by the ducheſs during the regency of the duke of Orleans, and was two years a priſoner in the Baſtille. After her liberation, the ducheſs, as a reward for her fidelity, married her to M. de Staal, lieutenant, and afterwards captain, in the Swiſs guards. From her own deſcription, ſhe appears to have poſſeſſed few perſonal attractions, yet her gallantries were a great ſource of the vexations with which her life was diſquieted. She ſometimes loved without a return, and ſhe ſometimes attracted attentions to which ſhe paid no regard. She died in 1750, and after her death were printed, in 3 vols. 12mo. "Memoirs of her Life," written by herſelf. Theſe are agreeably written, and in a pure and elegant ſtyle. There has been added a fourth volume, containing two comedies acted at Sceaux, entitled "L'Engoûment," and "La Mode," the chief merit of which is ſaid to conſiſt in the ſprightlineſs of the dialogue. Her memoirs have been tranſlated into the Engliſh language.

STAATEN LAND, in *Geography*. See *New* ZEALAND.

STAATSBERG, an opulent farming neighbourhood in Clinton, Ducheſs county, New York, in which is a poſt-office; 70 miles from Albany, and 10 from Poughkeepſie.

STAATZ, a town of Auſtria; 5 miles W. of Falkenſtain.

STAAVIA, in *Botany*, was ſo called by Dahl, in compliment to Mr. Martin Staaf, of Gottenburgh, a great patron of botany, and an aſſiduous diſciple of the great Linnæus, to whom he formerly communicated many natural productions from China.—Dahl. Obſ. Bot. 14. Thunb. Prodr. 41. Willd. Sp. Pl. v. 1. 1144. Ait. v. 2. 35. Poiret in Lamarck Dict. v. 7. 363. (Leviſanus; Schreb. Gen. 149, excluding the reference to Gærtner.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Rhamni*, Juſſ.

Gen. Ch. *Common Calyx* hemiſpherical, many-flowered, imbricated, of numerous linear leaflets. Perianth ſuperior, erect, of one leaf, in five deep acute ſegments, permanent. *Cor.* Petals five, ſhort, oblong, obtuſe, nearly upright, with ſlender claws. *Stam.* Filaments five, awl-ſhaped, inſerted into the bottom of the calyx; anthers roundiſh. *Piſt.* Germen inferior, turbinate; ſtyles two, combined, capillary; ſtigmas ſimple. *Peric.* Berry coated, of five cells. *Seeds* ſolitary. *Common Receptacle* convex, villous, or chaffy.

Eſſ. Ch. Flowers aggregate. Stamens inſerted into the calyx. Styles two, united. Berry coated, with five ſeeds. Common receptacle chaffy.

1. S. *radiata.* Rayed Staavia. Willd. n. 1. Ait. n. 1. (Brunia radiata; Linn. Mant. 2. 209. Phylica radiata; Linn. Sp. Pl. 283. Chryſanthemum ericoides coronatum; Breyn. Cent. 165. t. 82.)—Leaves lanceolate-triangular. Coloured rays of the calyx ſhorter than the diameter of the head of flowers.—Native of the Cape of Good Hope. A greenhouſe plant in England, flowering in May and June, but of no ſtriking appearance. The ſtraight hairy branches of the buſhy *ſtem* are clothed with numerous, little, alternate, heath-like, ſmooth, glaucous *leaves*, on ſhort ſtalks. The *flowers* are corymboſe, four or five together at the ſummit of each branch, looking not unlike ſome ſmall kind of *Aſter.* The diſk is a quarter of an inch broad, reddiſh. *Rays* nearly the ſame in length, pale, obtuſe, recurved.

2. S. *glutinoſa.* Clammy Staavia. Willd. n. 2. Ait. n. 2. (Brunia glutinoſa; Linn. Mant. 210.)—Leaves linear-triangular. Coloured rays of the calyx rather longer than the diameter of the head of flowers.—From the ſame country. Introduced into England by Meſſrs. Lee and Kennedy in 1793. We find no figure that can be truſted, though Plukenet's t. 431. f. 1. bears ſome reſemblance to this ſpecies. The *leaves* are longer and more ſlender than the foregoing. *Flowers* ſolitary, full twice as large, with copious, long, and ſlender rays. The *diſk* is glutinous, perhaps from abundance of honey, and is covered in the dried ſpecimens with ſand, whence the name.

STAB, in *Geography,* a town of Bohemia, in the circle of Pilſen; 11 miles S.S.W. of Pilſen.

STABAT *Mater Doloroſa.* This celebrated elegy in monkiſh rhymes, written about the 14th century by Jacoponus, a minor Franciſcan friar, has been ſet by all the great maſters in Italy, and Roman Catholic compoſers in Germany; but by none in ſo happy and captivating a manner as by Pergoleſi.

STABBIA, in *Geography,* a town of Etruria; 11 miles S.S.W. of Piſtoya.

STABBING, in *Law.* See MANSLAUGHTER.

STABBING *of Hoven Cattle,* in *Rural Economy.* See HOVEN.

STABILI SUONI, in the *Ancient Greek Muſic,* were the extremes, or loweſt and higheſt ſounds of each tetrachord, which, ſounded together, conſtituted the diateſſaron, or 4th, that was never changed as the two middle ſtrings were, which were elevated or lowered according to the genera, and on that account were called *mobiles, mobili ſuoni.*

STABLE, in *Rural Economy,* a building or houſe conſtructed for horſes and other animals, being furniſhed with ſtalls and proper contrivances to contain their food and other matter.

Nothing conduces more to the health of a horſe than the having a good and wholeſome ſtable. The ſituation of a ſtable ſhould always be in a good air, and on a firm, dry, and hard ground, that in winter the horſe may come in and go out clean. It ſhould always be built ſomewhat on an aſcent, that the urine and other foulneſſes may be eaſily conveyed away by means of drains or ſinks cut for that purpoſe.

As there is no animal that delights more in cleanlineſs than the horſe, or that more abominates bad ſmells, care ſhould be taken that there be no hog-ſtie, hen-rooſt, or neceſſary-houſe, near the place where the ſtable is to be built; for the ſwallowing of feathers, which is very apt to happen when hen-rooſts are near, often proves mortal to horſes; and the ſteams of a bog-houſe, or hog's dung, will breed many diſtempers; and particularly they will bring on the farcy and blindneſs in many horſes. It is much better to build the walls of a ſtable of brick than of ſtone, for the former is always dry, the other often ſweats, and is very apt to be damp, and to cauſe rheums and catarrhs to horſes that are ſet in the ſtable in damp weather.

The walls ought to be made of a moderate thickneſs, both for the ſake of ſafety, and warmth in winter, and to keep off the heat of the ſun in the midſt of ſummer, which would ſpoil the horſe's appetite, and ſink his ſpirits. The windows ſhould be made on the eaſt and north ſides of the building, that the north air may be let in to cool the ſtables in ſummer, and for the benefit of the riſing ſun all the year round, eſpecially in winter.

The windows ſhould either be ſaſhed, or have large caſements, for the ſake of letting in air enough; and there ſhould always be cloſe wooden ſhutters, that the light may be ſhut out at pleaſure; by which means the horſe will be brought to ſleep in the middle of the day, as well as in the night, when it is judged proper that he ſhould do ſo.

Many pave the whole ſtable with ſtone; but it is much better to have that part which the horſe is to lie upon, boarded with oak-planks; for it will be not only eaſier, but more warm and comfortable to the animal.

The boards muſt be laid as even as poſſible, for this is the way to make the creature lie moſt at his eaſe, and in the moſt healthful poſture. The dealers in horſes generally, indeed, make the boards be laid higher toward the top, and ſlanting down: this ſhews a horſe to more advantage as he lies, but it is very uncomfortable to the creature, and his hinder parts are always ſlipping down, and the hind legs are often made ſubject to ſwellings by it.

The planks ſhould be laid croſſwiſe, not lengthwiſe; and there are to be ſeveral holes bored through them to receive the urine, and carry it off underneath the floor into ſome drain or common receptacle. The ground behind ſhould be raiſed to a level with the planks, that the horſe may always ſtand even, and the floor behind ſhould be paved with ſmall pebbles, and the place where the rack ſtands ſhould be well wainſcotted. There are to be two rings placed on each ſide of the ſtall for the horſe's halter to run through, and a logger is to be fixed to the end of this, ſufficient to poiſe it perpendicularly, but not ſo heavy as to tire the horſe, or to hinder him from eating. The beſt place for him to eat his corn in is a drawer, or locker, made in the wainſcot partition; this need not be large, and conſequently need not take up much room, ſo that it may be eaſily fixed, and taken out to clean at pleaſure; by this means the common dirtineſs of a fixed manger is to be avoided.

Many people are againſt having a rack in their ſtables; they give the horſe his hay ſprinkled upon his litter, and if they think he treads it too much, or too ſoon, they only nail up three or four boards, by way of a trough, to give it to him in. The reaſon of this is, that the continual lifting up of the head to feed out of the rack is an unnatural poſture for a horſe, which was intended to take his food up from the ground, and makes him, as they expreſs it, withycragged. In the way of ſprinkling the hay on the litter, or laying it in a trough even with the ground, he not only takes it up as if from the earth in a natural way, but can eat as he lies, which is a kind of indulgence, that a horſe takes great pleaſure in.

It is proper, however, in moſt caſes, to have ſome ſort of rack, or other contrivance, for the purpoſe of containing the hay, or other ſort of fodder which the horſe may want, and from which he might eat it with eaſe and convenience to himſelf. The beſt and moſt economical kinds are probably thoſe which are placed in an upright manner in receſſes in the walls, or in the corners and angles of the ſtalls.

When there is ſtable-room enough, partitions are to be made for ſeveral horſes to ſtand in; theſe ſhould always allow room enough for the horſes to turn about, and lie down conveniently in, and they ſhould be boarded up ſo high toward the head, that the horſes placed in ſeparate ſtalls may not be able to ſmell at one another, nor moleſt each other any way. One of theſe ſtalls ought to be covered in, and made convenient for the groom to lie in, in caſe of a great match, or the ſickneſs of a valuable horſe. Behind the horſes there ſhould be a row of pegs to hang up ſaddles, bridles, and other neceſſary utenſils; and ſome ſhelves for the hanging up bruſhes, &c. and the ſtanding of pots of ointment and other preparations.

The ſtables of the nobility are often incommoded by bins for oats placed in them, which take up a great deal of room with very little advantage. Dr. Plott has given us, in his Hiſtory of Oxfordſhire, a very convenient method, uſed by a gentleman of that county, to prevent this. It is done by making a conveniency to let the oats down from above, out of a veſſel like the hopper of a mill, whence they fall into a ſquare pipe of about four inches in diameter, let into the wall, which comes down into a cupboard alſo let into the wall, but with its mouth ſo near the bottom, that there ſhall never be more than about a gallon in the cupboard at a time; which being taken out, and given to the horſes, another gallon immediately ſucceeds it from above, without any trouble to the groom or any body elſe. By this means there is not an inch of room loſt in the lower part of the ſtable where the horſes ſtand: and there is this great conveniency beſide, that the oats are always kept ſweet by it, for every gallon that is taken away puts the whole quantity above in motion, by the running down of the gallon that ſupplies its place, and no muſtineſs ever comes where there is this continual airing and motion. There may eaſily be contrived two of theſe, the one for the oats, the other for ſplit-beans; and both of theſe may be let into the range of preſſes, the oats and beans being ſeparated above by partitions. The other requiſites for a ſtable are, a dung-yard, a pump, and a conduit; and if ſome pond or running river be near, it is much the better.

But with regard to farm-ſtables, it is not, however, neceſſary to attend ſo much to elegance in their conſtruction as in the above caſes; it is ſufficient to have them neat, handy, and convenient. And in order to this, they ſhould be ſituated ſo as to be contiguous to the other offices, with which they may have the greateſt connection or relation.

It has been obſerved by Mr. Beatſon, in the firſt volume of Communications to the Board of Agriculture, that in the contriving and fitting up of the racks and mangers in theſe buildings, great attention ſhould be had to economy and the convenience of labour. The moſt common and uſual method of making them, ſo as to extend quite acroſs the upper end of the ſtall, is a bad and expenſive practice, and which has much inconvenience in the foddering of the horſes; as, in order to ſave trouble, ſervants are very apt to ſtuff the racks full of hay, however large they may be, from which many bad conſequences ariſe, and much hay is loſt or deſtroyed by being pulled down and mixed with the litter, or trodden under the feet of the animals. Beſides, various bad effects reſult from the practice of ſuffering horſes to be continually ſtuffing themſelves with hay, as is well known to thoſe who are accuſtomed to the proper management of ſuch animals; as under their directions they are never permitted to have much hay in their racks at a time. Another diſadvantage alſo attends this mode of fitting up ſtalls, eſpecially for farm-horſes, as it ought to be the object to preſerve every thing; the hay-ſeeds are totally loſt, which, if good, and carefully ſecured, might be of great utility and value. And by the practice of placing the racks with ſo much inclination outwards, the ſeeds are alſo very apt to fall into the horſe's ears and eyes, which often cauſe diſagreeable effects. For theſe reaſons, it is ſuppoſed that racks ſhould have a perpendicular direction, not having a ſpace of more than fourteen or ſixteen inches from the wall; the bottom being ſparred, in order to let the ſeeds fall down through below, whence they may be removed by a ſort of ſliding ſhutter. Theſe advantages may alſo be neatly and conveniently obtained by leaving niches in the walls for the racks, on which plan the ſpars will be equal with the inſides of the walls. Where the niches and racks are made in the middle of the ſtalls, two feet, or two feet and a half wide, will in moſt caſes be ſufficient; they ſhould, however, be carried down low enough to admit of a ſmall box or drawer being placed under them, for the reception of the hay-ſeeds. Racks of this ſort may likewiſe be placed in the corners of the ſtalls, and be made in ſuch a way, as that one niche may ſerve two ſtalls. And they may be placed in the angles of the ſtalls without having any niche, and may be made of a ſemicircular form. But in whatever way they are formed, there ſhould conſtantly be a diviſion betwixt them, which is probably beſt made of deal. Where the racks are put in the corners of the ſtalls, it may, perhaps, be more advantageous to have them ſtraight than circular; but in whichever way they are formed, the farmer ſhould always have a hatch fixed for each ſtall, as by that means a great deal of time may be ſaved in feeding his horſes.

If the above methods be adopted, it muſt be unneceſſary to make a manger of the ſame width with the ſtall; as a box or drawer, ſixteen or eighteen inches long, and twelve or fourteen inches wide, will anſwer every intention perfectly well. But it ſhould be ſo contrived that it may be readily taken out and cleaned whenever it is fouled, or becomes furred with dirt. With the fixed mangers this can never be done.

Beſides this, there is another method of making ſtalls, which, as being cheaper and more economical, deſerves to be regarded by the farmer: on this plan the ſtable has neither racks nor mangers; the head of the ſtall is boarded about three feet from the ground, having a ſpace of about two feet from the wall, in which the hay is to be depoſited, the horſe pulling his hay from below, inſtead of drawing it from above; which is not only more natural, but prevents the waſte of hay, much of which drops down and is loſt when the horſe eats from a rack. But even in this conſtruction, it will be neceſſary to have the bottom ſparred within eight or ten inches of the ground, and a box, hopper, or hay-manger and drawer, ſo contrived as to receive the ſeeds of the hay: where there are double ſtalls, the boxes may be divided in the middle. Single ſtalls, where they can be conveniently made, ſhould, however, always be preferred, as being much more ſafe and convenient in different points of view, both for the horſes and perſons employed about them.

Further, it is likewiſe conceived, that the paving of ſtables is a matter of great importance, though it has been hitherto but little attended to: whether the ſtall ſhould have a ſlight declivity, or be perfectly level, has not, perhaps, yet been ſo fully determined as it ought. It would appear, however, to be more natural and eaſy for theſe animals to ſtand and reſt themſelves on a level ſurface, than on one that is ſloping, as it is evident that the tendons or ſinews of the paſtern joints muſt be kept more upon the ſtretch in the latter than in the former caſe. The main difficulty in regard to a level ſtall has been the conveying away of the moiſture; but this may be well effected by paving the ſtall perfectly level, and only leaving a ſmall drain in the middle, extending within two or three feet of the upper end of the ſtall; but which ſhould not be more than ſeven or eight inches wide at top, forming an angle at the bottom. The depth at the end neareſt the head of the ſtall need not be more than three or four inches deep, having as much ſlope as can be conveniently given it backwards, in order that it may carry the moiſture off quickly to the main drain, into which all the ſtall-drains ſhould have a fall, and the moiſture be diſcharged. And the ſmall ſtall-drains muſt alſo be covered with a piece of good ſtrong oak-plank, in which a great number of holes are bored, and which muſt be ſo faſtened, as to admit of its being readily raiſed up and let down; as by this means the drains may be waſhed, and kept clean and ſweet, as often as they are found to be furred up and obſtructed. And beſides theſe, main drains muſt be made at the end of the ſtalls, or in ſome other convenient ſituation, for carrying off the moiſture into the general receptacle. Where they are placed at the bottoms of the ſtalls, they ſhould not be cloſer to the ſtalls than two feet, in order that the ſtale of mares may get readily into them, which would not be the caſe if they were nearer, unleſs the pavement behind the ſtalls was made to decline a little towards them. Theſe main drains need not be more than ſeven or eight inches wide at the top, but they ſhould be covered with plank, in which holes are perforated for conveying away the moiſture and wetneſs. But with the view of ſaving the expence of making main drains within the ſtable, a ſhallow open drain may be made in the common way, with which the ſtall-drains may communicate by means of very ſmall grates at the ends. And it ſhould be obſerved, that the pavements or floors of the ſtalls ſhould have a very ſlight declination from their ſides towards the drains, to prevent moiſture ſtanding on them; an inch, or an inch and a half in the whole, will, however, be quite ſufficient for theſs purpoſes.

It may be noticed, in regard to the ſizes of ſtalls, that they differ much according to circumſtances; but four feet and a half in width are the leaſt they ſhould ever be made, and five feet are much better. The diviſions between them ſhould be high, ſo that ſtrange horſes may not ſee each other. But where ſtallions are kept, or young horſes required to be left looſe in a ſtall, they ſhould be ſo incloſed as to be incapable of doing miſchief. And for theſe purpoſes, one or more ſtalls may be ſparred to the top, or doors provided, which may be hung to the back poſts of the ſtable. Where this laſt method is followed, the ſtalls ſerve extremely well for keeping different mares and their foals ſeparate from others, as well as many other uſeful purpoſes in the buſineſs of horſe-management with the farmer.

But the writer of the Eaſt Lothian Agricultural Survey has remarked, that ſometimes ſtalls are made double; and as farm-horſes generally work in pairs, each pair that work together have one of theſe double ſtalls; for horſes are ſocial animals, and it is ſaid they feed better, and are more cheerful, when they live in ſociety. But even in this caſe it is proper they ſhould be faſtened to the oppoſite ſides of the ſtall, and that each horſe ſhould have his own rack and his own manger; for although they may ſeem to have a very great attachment to each other, yet if the dividing of their food is left to themſelves, it is more than probable they will quarrel about it, and that the ſtrongeſt horſe will have the beſt ſhare. But ſuch farm-ſtables as contain only one row of ſtalls, with one horſe in each ſtall, are, on the whole, the moſt uſeful and convenient; and if the ſtalls are ſufficiently large, and the diviſions between them raiſed ſufficiently high, not with ſpars, as often is the caſe, but with boards cloſely joined, each horſe will be allowed to eat his proportion of corn and hay equally, and allowed to take the neceſſary reſt, without danger of being diſturbed by a troubleſome neighbour. The ſtable ought to be well paved, and of a ſufficient breadth, to leave a ſpace of at leaſt ſix or ſeven feet behind each horſe, for a ſafe paſſage to the ſervants in hanging the harneſs upon the wall, &c. The pavement ſhould decline very gradually from the horſe's head backwards, towards the channel at his heels, which ſhould alſo decline, in the ſame gradual manner, towards one end of the ſtable, where the urine may be received into a reſervoir. Proper openings ſhould alſo be left in the walls, for the purpoſe of ventilation; theſe ſhould be fitted with ſliding or flap-boards, opened in the morning, when the horſes go out to work, and ſhut in the evening: in this way the ſtables will be properly ventilated; and every riſk of cold, from having theſe openings uncovered during the night, be avoided.

The ſmell of a ſtable, where the dung has been allowed to remain for a week or ten days, is intolerable; and the volatile alkali generated is ſo ſtrong as to penetrate and affect both the eyes and noſes of perſons entering into it, in a very diſagreeable manner. The conſequence is, the horſes are ſickened and enervated by the heat and offenſive ſmell during the night; a part of their food, being impregnated with the effluvia, is loathed and rejected; and, in the morning, when they are taken out to work, inſtead of the ſprightly appearance exhibited by animals that have been well fed and had a comfortable bed, their hanging ears and heavy ſluggiſh appearance diſtinctly mark the ſtate of the ſtables they have quitted.

However, in order to render the forming and conſtructing of the different internal parts of ſtables more clear and eaſy, it may be neceſſary to have recourſe to ſome account and explanation of them. In the old common and uſual modes of placing the racks and mangers in ſtables, as in ſome meaſure ſuggeſted above, the former are moſtly put in a ſlanting outward upward direction, ſo as that the top parts of them may have a projection or ſpace of two feet or more from the walls, while the lower parts reſt againſt them. The latter are conſtantly placed a little below and underneath them, moſtly extending quite acroſs the ſtalls. In theſe modes of fixing theſe internal parts of ſtables, there is ſeldom or ever any ſort of contrivances for either preſerving the ſeeds, or preventing their falling upon the heads of the horſes, while they are eating. Nor is the hay, or other fodder, guarded againſt being pulled out, trodden under foot, and waſted by the animals. They are conſequently very uneconomical in their nature and conſequences.

But in the improved methods of placing theſe internal parts, the poſitions of the racks, as well as the nature, dimenſions, and other circumſtances of the mangers, are quite different. In ſome caſes, the racks are fixed about fourteen inches from the walls, with but very little, if any, ſlant; having their bottom parts laid with ſmall ſpars, or thin narrow pieces of wood, in an open manner, ſo that the hay-ſeeds can fall down through between them, and be received in a drawer, or box, made for the purpoſe below, where they are capable of being drawn or taken out at pleaſure. A ſmall box, or trough, is placed in ſome convenient part, anſwering the purpoſe of a manger, and which is ſometimes made as a drawer, to put in and draw out as there may be occaſion. The diviſions of the ſtalls ſometimes riſe pretty high at the head parts, in the ordinary way; and, at other times, in a curving manner at the upper ends, from the tail-poſts to nearly the ceilings of the ſtables; and flap-doors, the height of the lower parts of the diviſions, are ſometimes faſtened with hinges to poſts, or the walls behind the horſes.

In other inſtances, the racks are placed in half-circular niches or receſſes in the walls of the ſtables, oppoſite the diviſions of the ſtalls; each niche being made to ſerve two ſtalls, by having a diviſion in the middle betwixt them; and the racks themſelves are ſometimes made in half-circular forms. The ſame kind of half-circular racks are occaſionally alſo put in the angles or corners of the ſtalls, without any niches; there being diviſions between them, ſo as that they may ſerve two ſtalls: but the racks, in theſe caſes, have not always the half-circular form, but are made and fixed up in a ſtraight manner.

In all theſe caſes, ſmall drawers or boxes ſerve as mangers, for the horſes to eat their provender out of, as may be neceſſary. There are ſome few other modes of fixing up racks and mangers in ſtables, as will be ſeen below; but theſe are probably the moſt eligible and convenient, as well as the moſt economical and leaſt expenſive in their nature and means of putting up.

The manner of fixing the window and the ſhutters in the windows of ſtables is important in ſeveral reſpects, as they contribute much to the proper regulation of the atmoſphere and ſtate of heat in them, as well as to other matters. They are both probably the beſt and moſt convenient, when ſuſpended and balanced upon two iron pins, fixed in the middle parts of them, ſo as to render them capable of turning and ſtanding in either or any direction, and to be readily wholly removed, in caſe of neceſſity. When the windows are made to ſlide up and down, the ſhutters may alſo be fixed in this way with advantage and good effect. By theſe means the air may be eaſily let out or in, and be regulated in an exact manner, which will be of much advantage in different caſes and circumſtances of ſtable management. There is ſometimes a hopper ſort of contrivance in ſtables, where neither racks nor mangers are employed, which is broad at the top, and has about fourteen inches width in the bottom part; being ſparred, in order that the ſeeds may drop through into a drawer made for the purpoſe below. In each corner there is a ſmall box for corn, which ſerves as a manger; the hopper part being divided in the middle, ſo as to ſerve two ſtalls as hay-mangers. This is a neat and convenient mode in ſome caſes, though rather expenſive in making and putting up.

There are ſtill other contrivances in fitting up racks and ſtalls for preventing the unneceſſary waſte of labour and food, as well as to guard againſt the inconveniencies of hay-ſeeds falling into the eyes and ears of horſes, which have been ſuggeſted by experienced farmers in other countries. In one ſet of contrivances in this intention, the racks are placed in an upright manner, and the perpendiculars of them are made to fall on the inner edges of the troughs below, which have ſhelving leaves. In theſe caſes, when the animals pull out the hay from the racks, the waſte parts fall on the leaves, and thus ſlide down into the troughs, where they are ſecured from being ſpoiled by the breath of the horſes; while the diſtance between the bottoms of the racks and the troughs is quite ſufficient for the admiſſion of the heads of the horſes, ſo as that they may get at the hay which is dropped. The racks, in theſe caſes, are two feet four inches in depth, and two feet at top from the edge parts of them; being planed within, in order that the hay may fall to the bottoms of the racks gradually, in proportion as it diminiſhes in quantity, and the animals be ſaved the trouble of a long reach, which they are often obliged to make in the ſtables which are fitted up in the old uſual manner. The animals are fed and ſupplied with the fodder from the entry, which is ſix feet in width; the hay being dropped through a trap-door from the ſtore-room above the ſtable. This plan is the ſuggeſtion of Mr. Weſt, an intelligent North American farmer. Another plan in the ſame intention has been propoſed by Mr. Cooper, of another part of the ſame country, in which the racks of the ſtalls of the ſtables have a ſomewhat different conſtruction and poſition, being formed with what are called *ſlats*, or thin ſtrips or pieces of wood. In theſe the advantages are ſuppoſed to be very great, as the upright ſlats prevent the horſes from waſting the hay, as well as from blowing upon it: and beſides, the animals are prevented from looking round, a habit to which horſes are much accuſtomed when any perſon enters the ſtable; neither can they thruſt their heads over the troughs, as the ſlats compel them to feed directly over them, without turning to either ſide. This mode of fitting up the ſtalls of ſtables may be found of much utility, in different ſituations and circumſtances, in the management of both ſaddle, farm, and team-horſes.

Very great utility and ſaving in point of duration may not unfrequently be produced, by having the internal and ſome other parts of the mangers and boxes, or other contrivances from which the horſes eat their feeds of corn and other provender, lined and plated, or caſed with different metallic ſubſtances. At Holkham-Hall, in the county of Norfolk, Mr. Coke has his mangers themſelves, it is ſaid by the writer of the corrected agricultural account of that diſtrict, plated with ſheet-iron; and the front edges, which are rollers, covered with tin-plates. The bottoms of the ſtall diviſions are likewiſe made of ſlate. It has alſo been found that for ſtables, as well as all other offices, thoſe locks which have copper wards are the beſt, as being much more durable than any other kinds.

Stables, or the lofts over them, for ſaddle as well as for farm, team, and carriage-horſes, are alſo not unfrequently fitted up and provided with different ſorts of machinery and contrivances for preparing and reducing the different articles of food, which ſuch horſes are to have, into the moſt proper, convenient, and economical forms, for their being given to and conſumed by them. Theſe are, for the moſt part, ſtraw or chaff-cutters, bean, barley, or malt-crackers, and oat-cruſhing and bruiſing machines. Such contrivances are often of very great utility and convenience, when properly managed, and put up in ſuch ſtable buildings, or the rooms connected with them; and particularly where other more valuable uſes are to be made of ſtraw, pea and bean-haulm, and other ſimilar materials, than that of merely littering animals. They are likewiſe uſeful in ſaving much labour, by their being always ready and at hand for performing theſe different neceſſary operations, as well as in ſeveral other ways.

This ſort of machinery is arranged and placed in a variety of different ways, according to the circumſtances of the different caſes. In a two-ſtalled ſtable, paved in the manner which is directed above, or in that which has been recommended by a writer in the firſt volume of Communications to the Board of Agriculture, a very ſimple and convenient apparatus has been contrived for working a chaff-cutter and a bean and barley-cracker, ſituated in the upper part of it, by the Rev. Mr. Froud, of Dartington Parſonage, in the county of Devon, merely by the power of one horſe. It conſiſts, according to the writer of the corrected agricultural account of the huſbandry of the above diſtrict, of a block of oak ſunk in the ground below the ſtable, with a perpendicular ſhaft or ſtem paſſing through the hay-loft floor, upon the top of which is fixed a crown-wheel of two-inch elm-plank, with ſix caſt-iron ſegments, ſo as to compoſe a wheel of this ſort of one hundred and eight cogs. There is alſo a pinion-wheel with fourteen cogs, the ſhaft of which paſſes through a drum, which is eighteen inches in diameter. From this drum the motion is communicated by a belt to the barley-cracker, and by the ſame belt to the chaff-cutter, where it is drawn tight over a ſheave of eighteen inches in diameter. The barley-cracker has likewiſe a fly-wheel, and a wooden hopper for receiving the grain. The lever by which this machinery is worked, and which paſſes through a mortiſe made in the lower part of the ſhaft, makes, it is ſaid, the diviſion of the ſtalls of the ſtable, when tied or faſtened to the mangers and other parts.

Stables may, however, be accommodated with theſe ſorts of neceſſary machinery in other ways and manners, perhaps, with equal, if not greater, convenience and benefit than as above; as by having them put up in particular parts of ſuch buildings excluſively appropriated for them, and the materials which they are to work upon; or by placing them in diſtinct ſeparate erections conſtructed purpoſely for them, and ſuch matters in immediate connection with the ſtables. By either of theſe means every poſſible advantage may be gained, without the horſes being ſo much diſturbed as in the preceding method. Beſides, the materials which are to be operated upon may be a great deal more amply provided, and much better ſtored up and ſecured; and there will be far more extent for the fixing up and working of ſuch ſorts of machinery, as well as more room and convenience provided for putting by the different cut and prepared ſubſtances as food for the animals: and above all, a confidential ſervant can have the command and controul of ſuch ſituations, without interfering with the general management of the ſtables in ſuch inſtances, eſpecially where there is a proper corn and provender bin arranged ſomewhat in the manner that is ſuggeſted below; by which method a vaſt waſte and loſs of expenſive food may, in different caſes, be guarded againſt, and the machinery be wrought with a great deal more effect and ſecurity.

Stables for all ſorts of ſaddle-horſes, as well as for thoſe of the light carriage kinds, ſhould conſtantly be raiſed, conſtructed, and fitted up in a neat, warm, and ſometimes, in particular ſituations and circumſtances, in a rather elegant manner; as ſuch ſorts of horſes can never be made to look ſo ſleek and well in their coats as they ought to do, without the ſtables in which they are kept are in ſome degree warm and comfortable. And near the ſeats and reſidences of perſons of diſtinction, handſome ſtables have an ornamental effect, in conjunction with the other ſorts of offices and buildings, which is moſtly deſirable, and which ſhould ſeldom or ever be overlooked or neglected in the plans and diſtributions of the office-buildings, in ſuch caſes. The particular manner in which ſuch ſtables are to be built muſt be left to, and regulated by, the taſtes of the proprietors, and the peculiar nature and circumſtances of the ſituations; but in the external walls, effect ſhould almoſt always be well conſidered and attended to, while the neceſſary warmth and ſecurity are provided in an effectual and proper manner.

In the ſtalls, and the modes of fitting them up in theſe kinds of ſtables, the ſame ſort of neatneſs, elegance, and ornamental effect, ſhould, for the moſt part, be carefully preſerved and kept in view; though, in ſome caſes, this need not be ſo very much regarded. In the former, or ſtalls, there ſhould conſtantly be a ſufficiency of capacity or ſize, as already ſuggeſted, in order that the animals may not be too greatly confined, and that full room may be given for performing the various daily operations that are neceſſary about them. The latter, or the fitting up of the ſtalls, may be variouſly regulated and executed, according to the different methods and rules which have been laid down above, and the particular taſte of the owners; having a conſtant regard to neatneſs, ornament, convenience, and economy, in the diſtribution of the different kinds of food and labour which are neceſſary, and to be performed about them.

In the conſtruction of ſtables for farm and moſt ſorts of heavy team-horſes, a much leſs attention and regard to neatneſs will always be requiſite and proper; and any ſort of elegance or fineneſs in ſuch caſes muſt invariably be uſeleſs, abſurd, and improper. In the building and contriving of theſe ſorts of ſtables, convenience and the health of the animals are the principal circumſtances which deſerve to be materially conſidered and regarded. In the external incloſing materials for ſuch ſtables, any ſort which can afford the neceſſary warmth, ſhelter, and ſecurity, and which are at the ſame time cheap, will be proper for the purpoſe. The ſtables for theſe uſes need ſeldom, if ever, be raiſed to ſuch heights as thoſe for other ſorts of horſes; nor need they always have lofts over them, or, at leaſt, over the whole of them; though ſome extent of loft is moſtly deſirable, and often of conſiderable utility, for containing provender for the horſes in a convenient and readily applicable manner. A ſmall extent or proportion will, however, moſtly anſwer the purpoſe very effectually, when properly arranged and fitted up in ſuch intention; by which a very conſiderable ſaving of expence may not unfrequently be made.

The arrangement of all ſuch ſtables muſt be according to the nature and circumſtances of the farms, and purpoſes for which they are intended. The ſingle range or row mode, which has been already noticed, is very good, in many inſtances; but they may be quite differently arranged, placed, and ſituated, in other caſes, with equal or more advantage; and ſometimes, under particular circumſtances, ſtables with double rows of ſtalls may be found beneficial on farms, and for other uſes. In fitting up the internal parts of ſuch ſtables, the main objects are thoſe of convenience, the ſafety of the animals, the prevention of the waſte of food, and economy in the labour of thoſe who have the providing, preparing, and giving of it, as well as the management of the animals, in ſuch caſes.

Some have adviſed the having ſhort diſtinct ſtalls in ſtables, ſo that each horſe may conſume his feeds in a ſeparate manner, and be harneſſed and prepared for work with more facility and readineſs; and that the partitions, in ſuch caſes, ſhould not be carried quite up to the ceilings of the ſtables, in order that a more free and open circulation of air may be produced and preſerved. Others, again, contend for quite open ſhed-ſtables, where the racks and mangers are fixed low down near the ground; the horſes having ſmall yards for them to go into at pleaſure, furniſhed with pumps and ciſterns, as in theſe. With this ſort of management they are ſuppoſed to do better, even without dreſſing, than in regular ſtables, by the ordinary management which is beſtowed on them by farm-ſervants in ſuch caſes. Theſe ſorts of ſtables are ſaid to have anſwered well in practice, in ſome inſtances. They are found beneficial, when with yards, in the winter feeding of the horſes on dry fodder and carrots, or other ſimilar roots; alſo in ſummer, feeding them with different ſorts of green food and dry meat. It has been ſuggeſted, however, that as ſuch cold ſhed-ſtables ſeldom do well for horſes, thoſe of the regular ſtable kind may be the moſt proper in general, and eſpecially in all the more northern diſtricts of the kingdom; though the open ſhed ſort may ſometimes be uſeful and advantageous in the more ſouthern parts of the country, where the winter ſeaſons are more mild and favourable, as well as more ſhort in their duration. Low ſhed-ſtables, with large ſliding ſhutter openings behind the horſes, may often be cheap, proper, convenient, and uſeful, where ſoiling farm and team-horſes, during the ſummer ſeaſon, is practiſed to any great extent; as the animals, it is ſaid, not only do better in them, but are much more eaſily managed in ſupplying them with the different ſorts of green fodder in the moſt ſuitable and proper manner; and, at the ſame time, there are advantages produced in the way of raiſing manure. Theſe ſtables ſhould always be provided with ſuitable racks for the purpoſe; and there ſhould be proper drains for conveying away all the liquid matters that may be produced, in ſuch modes of feeding, into the littered yards, or other places deſtined for forming and containing the manure. They ſhould likewiſe have proper places provided in or near them, for the reception of the new-cut green food, from which it can be readily and with facility diſtributed to the different animals in ſmall ſuitable proportions, as it is wanted; there being large ſuitable openings into them, left for the purpoſe of receiving the carts, or other conveyances by which it may be brought to the ſtables. The horſes are probably the beſt and moſt advantageouſly managed, in all ſuch caſes, when kept conſtantly tied up in the ſtalls.

In all ſorts of ſtables, or very contiguous to them, as has been already ſuggeſted, there ſhould always be proper places provided for the reception and ſecuring of different ſorts of harneſs and other articles and things of that kind in; as well as ſuitable well-ſecured and convenient places for fixing up properly contrived corn-bins in. When theſe ſtables are ſmall, it is in general moſt convenient to have the corn-bins placed and put up in the rooms above them, and ſo contrived and conſtructed, as that the feeds may be regulated and drawn from a ſpout carried down into the ſtable part below, as by ſuch contrivances, much time, labour, trouble, and occaſionally food, may not unfrequently be ſaved, which would otherwiſe have been ſpent in going to the bins, meaſuring the grain or other ſorts of provender from them, and ſecuring them again. By having ſuch ſorts of contrivances duly provided in ſtables, many other ſorts of ſubſtances and materials, as food, can be kept ſafely and ready prepared, beſide thoſe of corn, either in a mixed or ſeparate ſtate, as may be moſt ſuitable and convenient; ſuch, for inſtance, as ſplit-beans, cut-ſtraw, bean and pea-haulm, and a great variety of other ſimilar matters, which are of much conſequence in the feeding and foddering of all ſorts of horſes.

On large farms, and in other ſituations where there is much room and convenience, it is always the beſt way to have ſuch cheſts, bins, or other contrivances, conſtructed and fitted up on the moſt improved principles, as thoſe of the aerated granary or ſome others, which have the means of preſerving the grain or other matters in a perfectly ſweet and ſound ſtate. Where the former of theſe plans is adopted and had recourſe to, the beſt form is probably that of ſomewhat the cubical, the bottom part being made, in ſome degree, in the manner of the common hopper, having the ſlider in the lower part of it ſo fixed and contrived, as that it may ſtand about eighteen or twenty inches from the floor of the place in which the bin or cheſt is put up; as by ſuch means, ſufficient room and convenience will be afforded for receiving and taking out the corn or other provender as it may be wanted. In all theſe kinds of bins or cheſts, the ſpouts for aerating the grain or other matters may with perfect eaſe, facility, and convenience, be formed and fixed from one ſide to the other of them; the external openings or air-holes being conſtantly well ſecured by gratings of iron-wire. In the ſpout parts of theſe bins, which moſtly project conſiderably below them, there are plate-iron ſliders at their bottoms, which are ſecured by a ſmall lock and key, where neceſſary. They have often alſo other ſmall ſliders put juſt above theſe, for the purpoſe of aſcertaining and regulating the feeds of the horſes, by which they can readily and without inconvenience be taken out as wanted for them.

The moſt uſeful and convenient machine for the uſe of ſtables, in cruſhing and bruiſing the grain and other ſubſtances which are neceſſary in them, is probably that conſtructed by Rawntree, as it takes up but little room, while it is very effective in reducing all ſuch materials. It is found to operate well on oats, beans, peas, barley, and other kinds of grain employed as horſe-food; and at the ſame time is capable of bruiſing malt for brewing.

Machines of the mill-kind are likewiſe ſometimes beneficial in ſtables for the purpoſe of preparing particular ſorts of horſe-food. The turning horizontal hand-mill, invented by Mr. Wright, may probably be found a good and uſeful contrivance for performing the neceſſary buſineſs in theſe ſituations, as it occupies but a very ſmall ſpace, is readily managed, and ſufficiently effective for the purpoſe.

It may alſo be of importance, that ſtables ſhould be better lighted than what is commonly the caſe, as the blindneſs which is ſo frequently met with among horſes, has lately been attributed, and not without conſiderable probability, to an exceſs of the ſtimulus of light on their coming out of dark or duſky ſtables, where the irritability of the organs of ſight has been for ſome length of time accumulating, into the full and broad glare of day-light.

As farm-ſtables are moſtly, during the ſummer months, very generally much expoſed to the full open air, the doors, wickets, or windows of them being very ſeldom ſhut, except at night, and then but very rarely; the conſequence of ſuch full expoſure is, that flies, which are attracted by the horſe-dung and other ſimilar matters, have very free acceſs into them; but as it may commonly be obſerved, that in ſuch expoſed ſtables, too, the ſpider is very prevalent, as is ſeen by the number of cobwebs which are preſent; it may, of courſe, be unwiſe and improper to diſturb or deſtroy them, as the inſect ſhould probably be cheriſhed in ſuch ſtables, as it may ſave the horſe from the irritation of a variety of little troubleſome enemies and diſturbers. The proviſion of ſuch an inſect is natural, and the uſeful conſequences of it ſhould not be diſregarded by the farmer in ſuch ſtables.

In concluding the account of ſtables, it may be juſt noticed, that the manner of treating and managing ſaddle and light carriage-horſes in them is often very negligent, uneconomical, and improper, as the different kinds of food which are made uſe of are not unfrequently given to them in very ineligible ſtates and modes, equally as to time, manner, preparation, and quantity; the natural habits or methods of feeding in the animals being ſcarcely at any time, or in any caſes or circumſtances, if they be ever at all attended to or regarded, ſo as to lead to better practices. The ſtuffing the racks of horſes in ſtables at all times and ſeaſons with large quantities of hay and other ſimilar ſorts of fodder, as is too commonly the caſe, is, in all circumſtances and caſes, a waſteful and highly improper manner of proceeding in ſtable-foddering. And the letting them have their feeds of corn or other ſorts of provender in irregular manners and quantities, is not leſs detrimental and inconvenient to the animals, than ſtuffing them ſo much with hay. They never ſucceed well when there is much irregularity in the practices of feeding them. All the other operations about them ſhould alſo be performed, as much as poſſible, in exact manners, and at proper periods.

But with the farm and heavy team-horſes, both in the ſtables and on the roads, as well as in other places, the manner of treatment is ſtill more exceptionable and improper in a variety of different diſtricts and ſituations of this country. It has been obſerved by Mr. Vancouver, that, except in Ireland, where the method of treating farm-horſes is extremely bad indeed, thoſe in the county of Devon have perhaps as hard a meaſure of neglect and ill-uſage dealt out to them, as is any where to be met with in the whole united kingdom. From the injudicious manner in which they receive the corn that is occaſionally given them, it is ſuppoſed, in ſome meaſure, a queſtionable point, whether it affords them a benefit, or, by diverting their appetites from the hay, pea-haulm, or other ſorts of ſtraw, abſolutely produces an injury and diſadvantage, in conſequence of the avidity with which they ſwallow the corn in an unmaſticated or unchewed ſtate. In order to rectify and remedy ſuch improper modes of management in the ſtable and other treatment of farm and heavy team-horſes, a better and more deſirable example, it is thought, can no where be found, than that which may be drawn from the management of farm and waggon-horſes in Pennſylvania and Maryland, in North America. Theſe horſes, it is ſaid, perform journies of two and three hundred miles over the ſtupendous mountains of that country, with prodigious loads of wheat and flour from the interior, and wet and dry goods from the ſea-ports to the different points of embarkation, at Fort Pitt, Red-ſtone, Charleſtown, Wheeling, and other places on the Ohio river. Notwithſtanding which, theſe waggon-horſes, through the whole extent of that country, are, it is aſſerted, ſeldom ſeen in a leſs high condition than the brewers' and other large cart-horſes in the metropolis of this country. The manner in which theſe American horſes are ſuſtained and ſupported, ſo as to perform theſe labours, is, it is ſaid, generally by feeding them, in the ſtables and on the roads, with hay and ſtraw chopped in ſhort pieces about half an inch in length, with which is mixed about half a peck of rye, oat, and Indian corn-meal, to about two and a half or three pecks of hay chopped in the ſame manner. A feeding-trough, ſufficiently large for four or five horſes to eat out of at the ſame time, is attached to each waggon, it is ſaid, while on the road. The chaff is put into this trough, and after being well mixed with the given quantity of meal, is moiſtened, and again well ſtirred together, until every ſhred or part of the hay or chopped ſtraw is found to be covered, or, as it were, froſted over by the meal. The avidity with which the horſes eat their meat or provender, when thus prepared, may, it is ſuppoſed, be readily conceived. Their feed or meal being finiſhed, they either purſue their journey or lie down to reſt; but in either caſe, it is obſerved, not without being well dreſſed, and perfectly freed and cleanſed from the muddy and other effects of their laſt labour. It is the pride and pleaſure, it is ſaid, of the carters, as well as of the waggon maſters in that country, to ſee their horſes in a condition rather above than under the labour which they have to perform; and in a hundred miles travelling, from Baltimore to Philadelphia, it is confidently aſſerted, that as many prime waggon-horſes, and in as high condition, may be ſeen, as is the caſe in any direction for the ſame diſtance from the chief city of this country. The adoption of a ſimilar manner of treatment in the management of farm and waggon-horſes in the ſtables and on the roads in this country, needs, it is thought, no further recommendation than the certainty of theſe facts and ſtatements, which are unqueſtionable.

The practice of baiting poſt, ſtage, and travelling horſes with rye, oat, or bean-bread, in the manner performed on the continent, is likewiſe, it is ſuppoſed, an infinitely more economical and facile mode of adminiſtering refreſhment to jaded, exhauſted, and labour worn-out animals, than that of giving them the crude corn in its unbroken ſtate, which is ſo commonly and indeed almoſt univerſally practiſed in this country.

That there are great waſte, want of economy, and loſs of nouriſhment, in the too general practice of giving unbroken corn to animals, eſpecially horſes, is extremely evident, from the ſtate it is in after it has paſſed through their bodies, as it is found, in many caſes of horſes thus fed, to have loſt but a little of its nutrient property, being ſtill capable of ſupporting other ſorts of animals, particularly thoſe of the granivorous kinds, in a perfect manner. In its unbroken condition, when not completely maſticated or broken by the teeth of the animals, as is frequently the caſe, the digeſtive proceſs of the ſtomach would ſeem to have but little effect upon it, as it paſſes in nearly its natural ſtate, while, when broken or cruſhed by art, it readily acts upon it, and the whole of its nouriſhing property is taken up there, and in its long courſe through the bowels, in conſequence of its being ſo much more fully and extenſively applied to their ſurfaces. All horſes are, therefore, far better fed and ſupported, where the grain is reduced in its preparation before it is given, than in the common uſual modes of giving it whole. The ſuppoſed defect from want of chewing and mixing the ſaliva of the mouth with it, where broken grain is given as the feeds of the animals, is probably complete ſuppoſition, being founded on an imperfect conſideration of the matter, and not upon the reſult of actual trials, as it has been a great deal talked about without any ſort of proof, which can be depended on, being given in its ſupport.

Stable *Bin* or *Hopper*, that ſort of box, or contrivance of that kind, which is fixed up in ſtables for the purpoſe and convenience of containing the corn or other ſort of provender, which is to be given to horſes in ſuch places.

Stable *Logger*, *Lumper*, or *Ball*, the oval, oblong, or round piece of ſolid wood, which has a hole through its middle, for the purpoſe of receiving and paſſing the rein of the horſe's head-ſtall or halter through, and faſtening it by a knot or otherwiſe, after it has been put through a ring fixed to the manger or other part of the ſtall, in order to poiſe and keep it tight, but not to be ſo heavy as to inconvenience the horſe in feeding or otherwiſe. There are often in good ſtables, two reins to each head-ſtall balanced in this manner. The forms and weights of theſe pieces of wood ſhould always be well ſuited and proportioned to the nature and powers of the horſes.

STABLE *Rings for Stalls*, the ſtrong iron rings which are fixed to the mangers or ſides of the ſtalls of ſtables for the purpoſe of the halter or head-ſtall reins of the horſes running in. There are not unfrequently two to each ſtall in well fitted up ſtables, but common ſtables have ſeldom more than one. Theſe rings are moſtly of the common kind, made ſo as to work in a ſhank, which ſcrews into the part of the ſtall to which the rings are to be fixed; but a great improvement has lately been made in them, by having them formed in ſomewhat the manner of and as a ſtrong ſpring, by which, in caſe of the horſe becoming entangled in the reins, accidents may be prevented by their giving way. At all other times they are as perfectly ſafe as the common ring. In theſe caſes, they have alſo a ſcrew-ſhank, in order to be fixed in their proper places, but are not moveable in it, as in the common ring.

STABLES's STRAIT, in *Geography*, a channel between Sugar-loaf iſland and Banker's iſland, in the Mergui Archipelago.

STABLESTAND, in the *Foreſt-law*, is when a perſon is found at his ſtand in the foreſt, with a croſs-bow or long-bow, ready to ſhoot at a deer, or elſe ſtanding cloſe by a tree with greyhounds ready to ſlip.

This is one of the four evidences, or preſumptions, by which a man is convicted of intending to ſteal the king's deer; the other three being back-berond, bloody-hand, and dog-draw. See FOREST.

STABLO, or STAVELO, in *Geography*, a town of France, in the department of the Ourte, and chief place of a canton, in the diſtrict of Malmedy, ſituated on the river Rechte, and deriving its name from that of an ancient abbey, founded in the year 657 by Sigebert, king of Auſtraſia, for the accommodation of St. Remacle, biſhop of Maeſtricht, who preferring ſolitude to the epiſcopal dignity, retired hither, and became the firſt abbot. The place contains 2604, and the canton 7903 inhabitants, on a territory of 292½ kiliometres, in 10 communes. The manufacture and trade, which are conſiderable, conſiſt of cloth and ſtuffs, and the tanning of leather; 20 miles S. of Aix-la-Chapelle.

STACCATO, Ital. is a term in *Muſic*, which implies a diſtinct ſeparation of one note from another, in a plain and articulate manner. The term is confined to inſtrumental muſic, and chiefly to that of the violin kind, where the ſtroke of the bow is to be given to every note, and none of the paſſages are to be ſlurred; that is, no two or more notes are to be played with the ſame bow.

STACHYS, in *Botany*, from ϛαχυς, *a ſpike*, becauſe the flowers, though whorled, are more crowded into a ſpiked form than moſt others of the ſame natural order; which may, in ſome meaſure, anſwer Ray's objection to this ancient name, as not peculiarly appoſite.—Linn. Gen. 293. Schreb. 390. Willd. Sp. Pl. v. 3. 97. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 632. Prodr. Fl. Græc. Sibth. v. 1. 407. Ait. Hort. Kew. v. 3. 397. Purſh v. 2. 407. Juſſ. 114. Tourn. t. 86. Lamarck Dict. v. 7. 364. Illuſtr. t. 509.—Claſs and order, *Didynamia Gymnoſpermia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, angular, permanent, cut about half way down into five awl-ſhaped, pointed, awned, rather unequal, teeth. *Cor.* of one petal, ringent; tube very ſhort; throat oblong, gibbous downwards at the baſe: upper lip erect, nearly ovate, vaulted, often emarginate: lower larger, reflexed at the ſides, three-cleft; its middle ſegment very large, emarginate, folded backward. *Stam.* Filaments four, two of them ſhorter than the reſt, all awl-ſhaped, curved towards each margin of the throat after flowering; anthers ſimple. *Piſt.* Germen ſuperior, four-lobed; ſtyle thread-ſhaped parallel to the ſtamens, and as long; ſtigma in two acute diviſions. *Peric.* none, except the ſcarcely altered calyx. *Seeds* four, ovate, angular.

Eſſ. Ch. Calyx five-cleft, awned. Upper lip of the corolla vaulted: lower reflexed at the ſides; its middle ſegment largeſt, emarginate. Fading ſtamens reflexed towards the ſides.

Stachys is chiefly an European genus, of herbaceous, or ſomewhat ſhrubby, moſtly perennial, plants. Loureiro indeed has a *S. Artemiſia*, found in China and Cochinchina; but we cannot, from his account, be certain as to its genus. Mr. Purſh enumerates four American ſpecies, three of which are new. The fourteenth edition of Linn. Syſt. Veg. contains ſeventeen, Willdenow has twenty-ſix. We ſhall particularize ſome of the moſt remarkable, eſpecially the five Britiſh ſpecies, and a new one from Crete.

S. *ſylvatica*. Hedge Woundwort. Linn. Sp. Pl. 811. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 416. Curt. Lond. faſc. 3. Riv. Monop. Irr. t. 26. f. 2. t. 34. (Galeopſis vera; Ger. Em. 704.)—Whorls of ſix flowers. Stem ſolid. Leaves heart-ſhaped, ſtalked.—Native of hedges and ſhady ſituations, throughout Europe, frequent with us, flowering in July and Auguſt. The *root* is ſomewhat creeping, perennial, not annual. *Herb* erect, two or three feet high, of a dark green, covered with fine, rather gliſtening hairs, and exhaling a pungent, diſagreeable, very peculiar ſcent. *Stem* ſolid. *Leaves* broad. *Spike* interrupted, leafy at the bottom, bracteated above. *Calyx* hiſpid. *Corolla* of a deep dull blood-red, elegantly variegated in front with purple and white.

S. *ambigua*. Ambiguous Woundwort. Engl. Bot. t. 2089. Ait. n. 5.—Whorls of ſix flowers. Stem hollow. Leaves oblong, heart-ſhaped at the baſe, ſtalked.—Found in the Orkneys, very abundantly, in potatoe-fields and other cultivated ground, as well as in the north of Scotland, and near the Pentland hills, flowering in Auguſt and September. It ſeems intermediate between *S. ſylvatica* and *paluſtris*, ſome ſpecimens more reſembling the former, others the latter. The *root* is white and creeping. *Stem* hollow, its hairs more or leſs deflexed. Lip of the *corolla* leſs ſtrikingly variegated. The ſtalked *leaves* diſtinguiſh this ſpecies from *S. paluſtris*; while their narrower oblong form, more ſilky ſurface, and the want of any very ſtrong fetor, render it unlike the *ſylvatica*.

S. *paluſtris*. Marſh Woundwort. Linn. Sp. Pl. 811. Willd. n. 4. Fl. Brit. n. 2. Engl. Bot. t. 1675. Curt. Lond. faſc. 3. t. 35. Riv. Monop. Irr. t. 26. f. 1. (Panax Coloni; Ger. Em. 1005.)—Whorls of ſix flowers. Leaves linear-lanceolate, half embracing the ſtem.—Found in marſhy watery places, about the banks of rivers, throughout Europe; common in England, flowering in Auguſt, and very troubleſome in low, wet cultivated fields. The *root* is fleſhy and tuberous, creeping extenſively, and very difficult of extirpation. *Stems* erect, two or three feet high, ſtrongly quadrangular, rough, with deflexed briſtles. *Leaves* ſeſſile, ſerrated; ſilky above; rather woolly beneath. *Spike* of many leafy whorls. *Corolla* light purple; its lower lip ſtreaked with white and violet. The herb is fetid. Gerarde calls it Clown's Woundwort, becauſe he was inſtructed by a clown to uſe it as a vulnerary, with ſo much ſucceſs, that, according to his account, it might ſuperſede all other ſurgical applications!

S. *germanica*. Downy Woundwort. Linn. Sp. Pl. 812. Willd. n. 6. Fl. Brit. n. 3. Engl. Bot. t. 829. Fl. Dan. t. 684. Jacq. Auſtr. t. 319. (S. Fuchſii; Ger. Em. 695.

S. montana; Riv. Monop. Irr. t. 27. f. 1.)—Whorls of many flowers. Leaves crenate. Stem woolly, erect.—Native of Germany, Siberia, France, England, and Greece. With us it is rare, occurring only on ſome chalky or limeſtone ſoils, flowering in July. The *ſtems* are denſely clothed with ſoft white wool. *Leaves* ſtalked, ovate, acute, covered with ſoft white pubeſcence, moſt woolly beneath. *Flowers* numerous, ſilky and ſilvery at the outſide; purple and white in front.

S. *lanata*. Woolly Woundwort. Murray in Linn. Syſt. Veg. ed. 14. 536. Jacq. Miſc. v. 2. 342. Ic. Rar. t. 107. Willd. n. 8. Ait. n. 9.—Whorls of many flowers. Leaves woolly. Stems procumbent and rooting at the baſe.—Native of Siberia. Frequent in gardens, where it proves a hardy perennial, flowering throughout the ſummer, and forming large tufts, conſpicuous for their very white woolly appearance. The *leaves* are more obtuſe, and far more denſely woolly, than in the laſt. Dr. Sibthorp's manuſcripts inform us that the preſent ſpecies is called ςαχυς by the modern Greeks in Laconia.

S. *coccinea*. Scarlet Chili Woundwort. Willd. n. 3. Ait. n. 3. Jacq. Hort. Schoenbr. v. 3. 18. t. 284. Curt. Mag. t. 666.—Whorls of ſix flowers. Leaves ovate, crenate, hairy; heart-ſhaped at the baſe, with dilated footſtalks.—Native of South America. Said to have been brought from Spain in 1798, by the late marchioneſs of Bute. This is a hardy greenhouſe plant, readily increaſed by cuttings, or by parting its roots, and producing abundance of large *flowers*, of that rich ſcarlet hue ſo prevalent in the vegetable productions of Chili and Peru.

S. *hyſſopifolia*. Hyſſop-leaved Woundwort. Michaux Boreal-Amer. v. 2. 4. Purſh n. 1. (S. paluſtris? Walt. Carol. 162.)—" Whorls of about four flowers. Stem erect. Leaves ſeſſile, linear-lanceolate, ſlightly toothed, nearly ſmooth."—Native of Carolina. A ſlender, upright, nearly ſmooth plant, with about four *flowers* in each *whorl*. *Michaux*.

S. *aſpera*. Harſh Woundwort. Michaux Boreal-Amer. v. 2. 5. Purſh n. 2. (S. tenuifolia; Willd. n. 11. S. arvenſis? Walt. Carol. 162.)—Whorls of about ſix flowers. Stem erect, very rough, with deflexed briſtles. Leaves lanceolate, acute, ſerrated, very ſmooth. Teeth of the calyx ſpinous, divaricated.—In low fields and on the banks of rivers, from New York to Virginia, flowering from June to Auguſt. It reſembles *S. paluſtris*. *Root* perennial. *Flowers* purple. *Purſh*.

S. *hiſpida*. Briſtly Woundwort. Purſh n. 3. (S. foliis lanceolatis, &c.; Gron. Virg. ed. 2. 89, but not the plant of Linnæus, nor of any other author cited, except Clayton, n. 271.)—" Whorls of about ſix flowers. Stem briſtly. Leaves ſtalked, ovate-oblong, bluntly ſerrated, briſtly. Calyx ſmoothiſh."—In old fields and low paſtures, from Virginia to Carolina, flowering in July. *Flowers* purple. Gronovius's ſynonym has been erroneouſly referred to *S. annua*, from which his original ſpecimen proves widely different. *Purſh*.

S. *Fœniculum*. Fennel-ſcented Woundwort. Purſh n. 4.—" Whorls of about ſix flowers. Stem erect, downy. Leaves ovate, ſomewhat heart-ſhaped, toothed; ſmooth above; whitiſh and downy beneath."—On the banks of the Miſſouri; annual, flowering in July. *Flowers* blue. The whole plant ſmells extremely like Fennel. *Purſh*.

S. *ſpinoſa*. Thorny Woundwort, Aſſes' Thyme. Linn. Sp. Pl. 813. Willd. n. 13. Ait. n. 12. Sm. Fl. Græc. Sibth. t. 559, unpubliſhed. (Gaidarothimo di Candia; Pon. Bald. 106.)—Hoary. Branches croſſing each other, tipped with ſpines. Flowers axillary, ternate.—Native of Crete, where moſt botanical travellers have gathered this ſpecies, and from whence it came into the gardens of Parkinſon and other curious cultivators of that time, though now ſcarcely to be met with. The *plant* is buſhy, of humble growth, ſpinous, pale green, with ſmall *leaves*. *Flowers* white, their lip prettily ſpotted with red.

S. *palæſtina*. Greek Woundwort. Linn. Sp. Pl. 1674. Willd. n. 15. Prodr. Fl. Græc. n. 1363. (S. alba, anguſto ſalviæ folio; Barrel. Ic. t. 279.)—Whorls of about ſix flowers, crowded, leafy. Leaves ſeſſile, lanceolate, entire, veiny, finely downy; as well as the nearly round ſtem.—Native of the Levant. Dr. Sibthorp found it plentiful throughout Greece, in rough and ſtony mountainous places, as Dioſcorides mentions of his ςαχυς, and therefore concludes it to be that identical ſpecies. It anſwers, indeed, well enough to the deſcription. The *ſtems* are erect, buſhy, ſomewhat ſhrubby, leafy, nearly round, clothed with peculiarly fine, cloſe, denſe, woolly hoarineſs. *Leaves* an inch and half or two inches long, ſcarcely one-third of an inch broad, very ſoft and downy on both ſides; the floral ones ſhort and ovate. *Calyx* unarmed, downy, like the outſide of the *corolla*, whoſe lips are purple, the throat variegated with white.

S. *rugoſa*. Rugged Yellow Woundwort. Ait. ed. 1. v. 2. 303. ed. 2. n. 17. Willd. n. 20. Jacq. Ic. Rar. t. 493.—Whorls of ſix flowers. Leaves lanceolate, ſerrated, rugoſe, downy; tapering at the baſe, and ſomewhat ſtalked. Stem round, finely downy.—Native of the Cape of Good Hope, from whence Mr. Maſſon is ſaid to have introduced it in 1774, yet Thunberg has it not in his Prodromus. The *ſtem* is ſhrubby, buſhy, quite round, very white, as in the laſt, to which the *leaves* alſo bear a great reſemblance, but are more ſtalked. Jacquin's plate ſhews no ſerratures. The *flowers* are axillary, with a white tube and yellow lips.

S. *annua*. Pale Annual Woundwort. Linn. Sp. Pl. 813. Willd. n. 23. Ait. n. 19. Jacq. Auſtr. t. 360. (Sideritis flore albo, barbâ luteolâ; Riv. Monop. Irr. t. 70. S. latifolia glabra; Ger. Em. 699.)—Whorls of ſix flowers. Leaves ovato-lanceolate, ſerrated, ſtalked, ſmooth, three-ribbed. Stem branched, erect.—Native of Germany and the ſouth of Europe. Kept ſometimes in curious gardens, rather for curioſity than any valuable property. The *root* is annual. *Stem* erect, ſquare, with oppoſite ſpreading branches. *Leaves* green; the larger ones ſtalked; uppermoſt narrower, and ſeſſile. *Calyx-teeth* ſpinous. *Corolla* white, with a yellowiſh lip.

S. *arvenſis*. Corn Woundwort. Linn. Sp. Pl. 814. Willd. n. 24. Fl. Brit. n. 4. Engl. Bot. t. 1154. Curt. Lond. faſc. 4. t. 41. Fl. Dan. t. 587. (S. arvenſis minima; Riv. Monop. Irr. t. 27. f. 2.)—Whorls of ſix flowers. Stem weak, ſpreading. Leaves heart-ſhaped, obtuſe, crenate, rather hairy.—Common in the fields of Britain, and other parts of Europe, eſpecially where the ſoil is light and ſandy, flowering in July and Auguſt. *Root* annual, ſmall. *Stems* ſpreading, often proſtrate, a ſpan long, ſquare, hairy or ſmooth. *Leaves* ſtalked, ovate, fetid, an inch long. *Flowers* ſmall, light purple, with a white and dotted palate; their *calyx* hairy, with violet teeth.

S. *ſpinuloſa*. Prickly-branched Woundwort. Prodr. Fl. Græc. n. 1368. (S. foliis hormini; Riv. Suppl. t. 15. Sideritis cretica maxima, ocymaſtri valentini facie; Tourn. Cor. 12.)—Whorls of ſix flowers. Leaves heart-ſhaped, crenate, hairy. Stem erect, branched, minutely prickly.—Native of Crete, where Dr. Sibthorp found it. Arduino ſent a ſpecimen to Linnæus, marked with Tournefort's ſynonym; and we have lately noticed a figure of this plant, in the rare unpubliſhed ſupplement to Rivinus, of which the only copy known to exiſt, apparently once belonging to the author, is in ſir Joſeph Banks's library. The *root* is fibrous, probably annual. *Stem* a foot or foot and half high, erect, branched, ſquare, with prickly angles. *Leaves* ſtalked, an inch and half long, bluntiſh, ribbed and veiny, green, more or leſs hairy. *Whorls* leafy, rather crowded. *Calyx* bell-ſhaped, hairy, with ſhort ſpinous teeth. *Corolla* yellowiſh, twice as long as the calyx; its upper lip entire.

STACHYTARPHETA, from *ϛαχυς, a ſpike,* and *ταρφυς, denſe,* a name of Vahl's, intended to expreſs the cloſe uninterrupted diſpoſition of the flowers.—Vahl Enum. v. 1. 205. Juſſ. Annal du Muſ. v. 7. 75. Ait. Hort. Kew. v. 1. 46.—Claſs and order, *Diandria Monogynia.* Nat. Ord. *Verbenaceæ,* Juſſ. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, angular, with four acute teeth, permanent. *Cor.* of one petal, ſalver-ſhaped; tube cylindrical, longer than the calyx, ſomewhat recurved at the upper part; limb ſpreading, divided half way down into five roundiſh unequal ſegments, the loweſt being the ſmalleſt. *Stam.* Filaments four, inſerted into the upper part of the tube, not reaching to its top, two of them imperfect; anthers of two cells, one over the other. *Piſt.* Germen ſuperior, two-lobed; ſtyle the length of the tube, capillary; ſtigma peltate. *Seeds* two, linear, the length of the calyx.

Eſſ. Ch. Calyx tubular, with four teeth. Corolla ſalver-ſhaped, unequal, five-cleft, curved. Two abortive ſtamens. Seeds two.

A handſome and diſtinct genus, of tropical, chiefly Weſt Indian, annual or ſhrubby plants, previouſly confounded with *Verbena.* Their *branches* are obſcurely quadrangular, divided in a forked manner in the upper part. *Leaves* oppoſite, ſtalked, tapering down into the footſtalks. *Spikes* from the forks and ſummits of the branches, ſolitary, elongated, cylindrical, tapering, acute. *Flowers* alternate. *Bracteas* tapering into a briſtly point. *Calyx* as long as its correſponding channel in the common ſtalk.

Twelve ſpecies are defined by Vahl.

1. S. *anguſtifolia.* Narrow-leaved Baſtard Vervain. Vahl n. 1, excluding Jacquin's ſynonym. (Verbena anguſtifolia; Mill. Dict. ed. 8. n. 15.)—"Leaves lanceolate, tapering at each end, diſtantly ſerrated, ſmooth."—Gathered at Vera Cruz, by Houſtoun, who ſent ſeeds to Miller. The latter deſcribes it as an annual branching plant, a foot and half high. *Leaves* pale green, acute, three inches and a half long, half an inch broad. *Spikes* fleſhy. *Flowers* blue, appearing in Auguſt, and in warm ſeaſons ripening ſeed in our gardens.—We agree with Vahl that Miller's plant, though we have not ſeen it, is probably diſtinct; but Jacquin's *indica* ſurely is the following.

2. S. *indica.* Indian Baſtard Vervain. Vahl n. 2. Ait. n. 1. (Verbena indica; Linn. Sp. Pl. 27. Jacq. Obſ. faſc. 4. 7. t. 86.)—Leaves lanceolate-oblong, tapering at the baſe, coarſely toothed, ſmooth as well as the ſtem. Bracteas linear-lanceolate.—Native of Ceylon. Van Royen ſent ſeeds to Linnæus, who raiſed the plant in his ſtove. It is annual, flowering in Auguſt and September. The *leaves* are an inch or more in breadth; the lower ones obtuſe. *Spikes* long and ſlender. *Bracteas* finely ſtriated, membranous at the edges. *Corolla* blue. Jacquin repreſents the *leaves* more narrow and acute, with more regular ſerratures, than in the Linnæan ſpecimen, which came from the Upſal garden, and is accompanied by a branch with narrower leaves. This latter, evidently a mere variety, may be ſimilar to what Vahl had from the ſame garden, and took for Miller's *Verbena anguſtifolia.*

3. S. *ariſtata.* Awned Baſtard Vervain. Vahl n. 3. (Verbena ariſtata; Vahl Ecl. Amer. v. 2. 2. t. 11.)—"Leaves oblong, ſerrated, acute; villous and ſlightly hoary beneath. Bracteas ovate, pointed. Stem ſhrubby."—Gathered by Von Rohr in South America. *Branches* purpliſh-grey. *Leaves* an inch and a half long, tapering at each end, equally and deeply ſerrated, entire at the baſe, ribbed; the ribs moſt hoary underneath. *Spike* ſometimes near a foot long. Lower *bracteas* ſpreading; upper imbricated, ſomewhat fringed, longer than the *calyx. Vahl.*

4. S. *jamaicenſis.* Jamaica Baſtard Vervain. Vahl n. 4. Ait. n. 2. (Verbena jamaicenſis; Linn. Sp. Pl. 27. Jacq. Obſ. faſc. 4. 6. t. 85. V. folio ſubrotundo ſerrato, flore cæruleo; Sloane Jam. 171. t. 107. f. 1. Cymburus urticifolius; Saliſ. Parad. t. 53.)—Leaves ovate, obtuſe, ſerrated, nearly ſmooth. Branches hairy. Bracteas ovate, ſhorter than the calyx.—Native of the Weſt Indies. Introduced very early into our ſtoves. The *ſtem* is naturally ſhrubby and perennial, though it ſeldom ſurvives after flowering in a hot-houſe. *Leaves* two inches long, tapering down into a winged *footſtalk* half that length; their veins and margins roughiſh with ſhort hairs. *Spikes* a ſpan long, hardly thicker than a crow's quill. *Bracteas* cloſe-preſſed. *Corolla* blue, ſomewhat reſembling the elegant *Duranta Elliſia.*

5. S. *dichotoma.* Forked Baſtard Vervain. Vahl n. 5. ("Verbena dichotoma; Fl. Peruv. v. 1. 23. t. 34.")—"Leaves oblong-ovate, ſerrated. Branches hiſpid. Bracteas lanceolate, the length of the calyx."—Native of woods in Peru. *Stem* ſhrubby, erect, a yard high, ſlightly branched; the branches compreſſed in each joint at the upper part. *Leaves* acute, veiny, minutely hiſpid beneath; their ſerratures pointed. *Spikes* a foot long, curved. *Seeds* ſtriated externally. *Fl. Peruv.*

6. S. *marginata.* Bordered Baſtard Vervain. Vahl n. 6.—"Leaves roundiſh-ovate, ſmooth, with tooth-like ſerratures; the edges of the teeth cartilaginous. Stem ſhrubby."—Found by Von Rohr in the Weſt Indies. *Branches* round, ſmooth, like the reſt of the plant. *Leaves* an inch long, firm, very obtuſe, ribbed, without veins, with pointed coarſe teeth. *Spikes* ſix inches long, as thick as a pidgeon's quill. *Bracteas* linear-lanceolate, tapering, the length of the calyx, finely ſtriated. *Vahl.*

7. S. *ſtrigoſa.* Strigoſe Baſtard Vervain. Vahl n. 7.—"Leaves ovate-oblong, crenato-ſerrated, hairy like the branches."—Native of the Weſt Indies. *Ventenat.* Shrubby, with round *branches,* which are beſprinkled, like the *leaves* and *footſtalks,* with white hairs. *Leaves* very blunt, an inch long, ribbed, veinleſs. *Spikes* no thicker than packthread, about four inches long. *Vahl.*

8. S. *cajanenſis.* Cayenne Baſtard Vervain. Vahl n. 8. (Verbena cayennenſis; Richard Act. Soc. Hiſt. Nat. Pariſ. v. 1. 105.)—"Leaves ovate, crenato-ſerrated, ſmooth, very obtuſe. Stem ſhrubby."—Native of Cayenne. *Branches* round, their young extremities hairy, as well as the *flower-ſtalks* and the *leaf-ſtalks. Leaves* two inches long, coarſely crenate, ribbed. *Spikes* ſlender, four inches in length. *Bracteas* ſlender, hairy like the *calyx. Vahl.*

9. S. *orubica.* Orubian Baſtard Vervain. Vahl n. 9. Ait. n. 3. (Verbena orubica; Linn. Sp. Pl. 27. Pluk. Almag. 382. t. 228. f. 4, and t. 327. f. 7. Sherardia urticæ folio ſubtùs incano, floribus violaceis; Ehret. Pict. t. 5. f. 1.)—Leaves ovate, ſerrated, rough and rugoſe. Stem ſhrubby. Bracteas ovate, larger than the calyx.—Native of Panama. A greenhouſe or ſtove ſhrub, early introduced, but not often met with in our collections. The *ſtem* is a yard high, branched. *Leaves* deeply ſerrated, rounded. *Spike* twelve or eighteen inches long, with ſquarroſe *bracteas. Corolla* violet, with a dark divided ſpot.

10. S. *mutabilis.* Changeable-flowered Baſtard Vervain. Vahl n. 10. Ait. n. 4. Curt. Mag. t. 976. (Verbena mutabilis; Jacq. Coll. v. 2. 334. Ic. Rar. t. 207. Andr. Repoſ. t. 435. Venten. Malmaiſ. t. 36. Cymburus mutabilis; Saliſ. Parad. t. 49.)—Leaves ovate, ſerrated, rugoſe, ſomewhat hoary as well as the ſtem. Bracteas lanceolate, ſhorter than the calyx.—Native of South America. A ſtove-plant, flowering throughout the ſummer, and propagated by cuttings. This is larger and more ſplendid than any of the foregoing. *Leaves* often four inches, or more, in length. *Spikes* a foot long. *Flowers* large, crimſon, with a central ring of a blood-red, round the white throat. The *corolla* fades before it goes off, occaſioning a perpetual variety of hues in each ſpike.

11. S. *priſmatica.* Germander-leaved Baſtard Vervain. Vahl n. 11. Ait. n. 5. (Verbena priſmatica; Jacq. Coll. v. 2. 301. Ic. Rar. t. 208. V. ſpicata jamaicana, Teucrii pratenſis folio, diſpermos; Pluk. Alm. 382. t. 321. f. 1.) —Leaves ovate, obtuſe, ſerrated. Spikes lax. Bracteas awl-ſhaped, ſhorter than the calyx.—Native of the Weſt Indies. Biennial in our hot-houſes, flowering in May and June. The *ſtem* has many ſmooth, ſlender, forked branches. *Leaves* one or two inches long, green, roughiſh, ribbed. *Flowers* fewer and more diſperſed than in the reſt, of a violet blue, ſmall and rather inconſpicuous.

12. S? *ſquamoſa.* Scaly Baſtard Vervain. Vahl n. 12. (Verbena ſquamoſa; Jacq. Hort. Schoenbr. v. 1. 3. t. 5.) —Leaves elliptic-lanceolate, alternate, with ſhallow wavy ſerratures. Flower-ſtalks axillary, ſcaly, much longer than the leaves. Stem ſhrubby. Corolla ringent.—This flowered in the imperial ſtoves at Schoenbrun, but its native country is unknown. We ſhould preſume the plant to be of South America origin. The *branches* are villous. *Leaves* dark green, ſpreading, three inches long. *Flower-ſtalks* very peculiar, numerous, from five to ten inches long, hairy, thread-ſhaped, ſometimes branched, covered entirely with innumerable cloſe *bracteas.* *Flowers* very ſmall, pale blue; their upper lip erect, ſhort, cloven; lower larger, ſpreading, in three cloven ſegments. Vahl has doubts reſpecting the genus of this plant, its leaves being alternate. We ſuſpect it to be more allied to *Juſticia;* at leaſt to the Linnæan *J. acaulis,* which is Vahl's *Elytraria crenata.*

STACK, North, in *Geography,* a cape on the W. coaſt of the iſland of Angleſea; 2 miles N. of Holyhead.

Stack, in *Agriculture,* a quantity of corn, pulſe, hay, ſtraw, ſtubble, or other ſimilar material, regularly built or piled up, and generally thatched, as a defence from the weather. Stacks are of various forms and dimenſions, according to circumſtances; but for grain, thoſe of the long, narrow, ſquare ſhape are probably the moſt advantageous, where the quantity of corn is conſiderable; as they are found to ſtand more firmly, have a better appearance, are more conveniently and readily built, and preſerve the grain better than thoſe of other forms. And they have the great advantage of requiring leſs thatch, as well as labour in putting it upon them. But where the corn is only in a ſmall proportion, the round or oblong ſhape may be more proper and ſuitable, as being more readily drawn up in the roof; and the circular, with a conical top and cylindrical body diverging a little at the eaves, is eſteemed the beſt form of any in ſuch caſes by the author of the Agricultural Report of Perthſhire. For hay, the form of the ſtack is a matter of ſtill leſs conſequence: the long ſquare or oblong ſhapes are perhaps the moſt ſafe and convenient, eſpecially when not too broad, as they admit the air the moſt fully. Beſides, they are the moſt convenient to cut from in truſſing hay for ſale at the market. But the circular form for farm uſe, where ſtraw is ſcarce, may be more advantageous in ſaving ſtraw in thatching or covering them.

The octagonal form of corn-ſtack has ſometimes a pleaſing and very ornamental effect in particular circumſtances and ſituations, eſpecially in the ſtack-yards of the farms about country ſeats and reſidences, but it requires more time and trouble in building and finiſhing than thoſe of moſt other ſhapes, conſequently is improper, in general, except in ſuch places, circumſtances, and ſituations.

The oblong and long ſquare forms of corn-ſtacks, with circular ends in the latter caſe, are ſometimes very convenient, uſeful and advantageous, as they are built and finiſhed in a ready and eaſy manner, take up but little room in compariſon with ſome other forms, and keep the grain remarkably well and ſafe. In building them, the different courſes of the ſheaves, which are not many in the width, are laid ſo as to bind on each other and ſecure the whole, as will be ſeen in ſpeaking of ſtacking grain in a more full and clear manner.

In the ordinary circular form of corn-ſtack, the thatch, which ſhould always come down to the termination of the moſt bellying-out or ſpreading-out part of the ſtem, is uſually ſecured and kept on in the common way, without the uſe of any ſort of rope or other contrivance of that kind. Ropes are, however, ſometimes employed.

But there is another form of corn-ſtack, which is common in the northern parts of this country and that of Scotland, which is of the round kind, and which moſtly reſts on a wooden frame upon high ſtone ſupports with flat caps. The ſtem is made perfectly upright to the eaves, where the ſheaves of the upper part are made to project ſome way at firſt, and then gradually taken into a point at the top. The thatch or covering in this caſe, in conſequence of the windy and ſtormy ſituations in which the ſtacks are moſtly expoſed, are, for the moſt part, ſecured by means of ſtraw-ropes, or thoſe of other kinds, put on in a ſort of chequered manner, one rope being made to croſs or paſs over the other, ſo as to afford ſomething of this appearance. There are two ſtraight ropes, to which all the others, which are oblique, are faſtened, the ends being well ſecured by being paſſed round a ſtrong belt-rope which ſurrounds the top of the upright ſtem of the ſtack. The different oblique ropes are put on alternately from the different ſides of the ſtack. In ſome caſes, the ends of the oblique ropes are fixed to the butt-parts of the ſheaves, without any ſort of belt-rope being employed. See Thatching *of Grain-Stacks.*

There are a few other forms of corn-ſtacks, which are occaſionally made uſe of in particular circumſtances and caſes of farms; but more for the ſake of curioſity, than any utility they may have in practice.

In ſtacks with any ſort of pulſe crops, as peas, beans, feeding tares, and other ſimilar matters, the ſame forms may be moſtly had recourſe to, but their ſtem-parts need ſeldom be ſo much bellied out at the eaves as in corn-ſtacks, as there is moſtly leſs danger from wet; they ſhould always, however, have ſo much outward diverging at the tops of the ſtems, as fully to carry off the water from them. The ſtalk or butt-ends of all ſuch ſorts of produce, when put into ſtacks, ſhould conſtantly be carefully laid in an outward direction, ſo that as few of the pods as poſſible may be expoſed to the moiſture of the air. The top-parts in ſtacks of this kind have rarely any occaſion to be carried up to ſo much height, as is the caſe ſometimes in corn-ſtacks. Theſe ſorts of ſtacks, as well as thoſe of corn, ſhould always be put on ſtands or ſtaddles which are conſiderably raiſed from the ground.

In the forms of hay-ſtacks there is leſs variety than in thoſe of corn, but they have ſome degree of variety according to circumſtances, and the nature of the ſituations in which they are placed, as well as ſome other cauſes. The moſt uſeful forms are probably thoſe of the ſquare, long ſquare, oblong, and perfectly round kinds. There is a curious ſort of low very bellying form, which reſts on a very ſmall baſis or ſtaddle at bottom, and which has an equally low top, which is ſometimes in uſe. This is ſomewhat the form or ſhape of a ſort of hay-ſtack, which in Scotland, and ſome of the more northern Engliſh diſtricts, is often denominated a hay-ſow.

In ſtacks with hay of the artificial graſs kinds, as that of clover, ſaintfoin, tares, and other ſimilar ſorts, the ſtacks ſhould never be made ſo large as in the caſe of natural graſs-hay, as ſuch ſorts of hay, in order to ſecure them in the beſt manner, ſhould never be ſo much or ſo well made as that of the natural graſs kind; conſequently never be put together in ſtacks in ſuch large quantities, as there may often be danger, inconvenience, and loſs in ſuch practices.

In ſtacks of the ſtraw and ſtubble kinds, very little more is ſeldom neceſſary than merely the ſecuring of the materials; they need but rarely have ſo much labour and time beſtowed upon forming the top-parts of them, as is often the caſe in corn and hay-ſtacks, as the matters ſcarcely ever remain in them for any great length of time, being moſtly in a ſtate of gradual removal for different uſes.

It may be farther obſerved, in reſpect to the ſizes of ſtacks of the firſt ſort, that they of courſe vary greatly according to circumſtances; but they ſhould never be made too large, as there is a great deal more labour and riſk in ſecuring and getting in the grain for them, than in thoſe of a ſmaller ſize; and from their being built at different times, they do not ſettle altogether in ſo equal and perfect a manner, or reſiſt the effects of the weather, and keep the grain ſo well, as thoſe of leſs dimenſions, that can be completed at once: and, in addition, they are more convenient in the threſhing out, eſpecially where the flail manner is employed. The chief advantages they poſſeſs are thoſe of taking ſomething leſs in thatch and labour in covering them, as has been juſt noticed. But, in common, from about twenty to thirty-two horſe cart-loads may be ſufficient for one ſtack, on all the middling-ſized farms in moſt of the grain diſtricts of this kingdom.

And in regard to the proper ſize of the hay-ſtack, it ſhould probably be different in ſome degree, according to the ſtate and nature of the hay; but a middling ſize is perhaps the beſt, as from twenty to thirty loads of about one ton each; as there are inconveniencies in both ſmall and large ſtacks, the former having too much outſide, while the latter are liable to take on too much heat, and at the ſame time permit leſs moiſture to be preſerved in the hay. In ſmall ſtacks, the bellying forms, with very narrow bottoms, have often much advantage, and are in ſome diſtricts termed ſheep-ſtacks, probably from the ſlovenly practice of ſheep having been permitted to feed at them. It is obſerved by Mr. Middleton, in his Agricultural Survey of Middleſex, that there are no hay-ſtacks more neatly formed nor better ſecured than thoſe of that county. At every vacant time, while the ſtack is carrying up, the men are employed in pulling it with their hands into a proper ſhape; and about a week after it is finiſhed, the whole roof is properly thatched, and then ſecured from receiving any damage from the wind, by means of a ſtraw-rope extending along the eaves, up the ends, and near the ridge. The ends of the thatch are afterwards cut evenly below the eaves of the ſtack, juſt of ſufficient length for the rain-water to drip quite clear of the hay. When the ſtack happens to be placed in a ſituation which may be ſuſpected of being too damp in the winter, a trench of about ſix or eight inches deep is dug round, and nearly cloſe to it, which ſerves to convey all the water from the ſpot, and renders it perfectly dry and ſecure.

It may be noticed, that in ſtacks of all kinds, proper ſtands or ſtaddles ſhould conſtantly be provided, being well proportioned to the intended ſize of the ſtacks. Thoſe for grain ſhould have copings placed ſo as to prevent the entrance of vermin: but for hay there is no neceſſity for this, nor need they be raiſed ſo high, but be quite plumb and upright. It is evident, that by the common method of placing them upon the ground, on a little drift, or a few pieces of wood laid acroſs each other, there muſt conſtantly be great loſs in the bottom parts of the ſtacks, from the moiſture being abſorbed by the hay, and it becoming in a fuſty condition; while by the uſe of ſtands, this may be almoſt wholly avoided, and the expence be but trifling, as any old rough pieces of wood, or other materials, will anſwer the purpoſe in a pretty perfect manner, when other better ſorts of ſtaddles are not at hand, or to be procured. See STADDLE and STAND.

All ſorts of ſtacks ſhould be carefully attended to, while they are forming and getting up, and never be left for any length of time, as is too frequently the caſe, without being properly topped up; as injury and loſs are always to be apprehended wherever that is the caſe. Every kind of ſtack ſhould likewiſe conſtantly be ſuffered to have completely ſettled in all its different parts, before it be attempted to be covered in; as otherwiſe the covering may be deranged and rendered unſightly, by the ſhrinking that may afterwards take place, and the matters be not rendered ſo ſecure or ſo well preſerved.

Stacks of the corn kind are ſometimes conveniently placed upon low frames of wood, and on low caſt-iron wheels, moving in circular iron railways, contrived in ſuch a manner as that three or four horſes may, in moſt caſes, in moderate ſized ſtacks, draw them to the barn or threſhing machine. Placing them on theſe ſorts of contrivances is often of great utility and advantage, in ſaving the expence of labour and time in carting, or otherwiſe conveying them to ſuch places; and is, beſides, capable of being performed at any time, without waiting for the coming of fine and favourable weather for the purpoſe. The expence in this way of placing ſtacks is very trifling, and will in a great meaſure prevent the neceſſity of having capped ſtone ſtandings for them. It is likewiſe a neceſſary and uſeful plan, in many inſtances, as being that alone which allows of a choice of any particular ſtack for threſhing, without waiting for the whole or a great number of others being previouſly removed or taken out of the way. In ſome other caſes the placing the ſtacks in ſtraight lines, leading by and paſt theſe places, may anſwer the ſame intention, though in a much leſs perfect manner in different points.

STACK, *Hay-Sow*, a name given in ſome places to that low bowl-like bellying form of ſtack, which has an equally low top, ſecured by hay, or other ſimilar kinds of ropes, put on in ſomewhat the checquered form. It is chiefly in uſe in ſuch ſituations as are much expoſed to winds and ſtorms.

STACK, *Mow Ariſh* or *Erriſh*, that particular ſort of ſtack or mow which is made with grain in the field, in ſome diſtricts, as Cornwall, in wet and catching harveſt ſeaſons. The corn uſually remains in theſe ſtacks for a fortnight or three weeks. And it is ſaid by the writer of the corrected account of the agriculture of the above county, that theſe ariſh ſtacks or mows, of which he has given a repreſentation, are admirable contrivances in ſuch like ſeaſons; and that if proper care be taken in forming and making of them, to keep the middle parts well up, ſo as that the butt-ends of the ſheaves may have a conſiderable ſlope outwards, the corn will receive no damage, though it were to remain in the field a month or ſix weeks, or perhaps longer. See STACKING *Grain.*

STACK, *Sheep Hay*, a name ſometimes applied to that ſort of low, circular, diverging form of hay-ſtack, in ſome diſtricts, which was formerly had recourſe to about farms, for ſheep to feed at during the ſeverity of the winter ſeaſon. This littering, waſteful, and ſlovenly mode of foddering ſheep has now moſtly been done away by the great value of hay, and the introduction of proper ſheep-yards, with ſuitable contrivances for the purpoſe. See SHEEP-*Yard.*

STACKS, *Supporting of*, the practice of propping and ſhoring them up, where they may happen to lean or incline too much to either ſide, ſo as to be in danger of falling without ſuch aid and aſſiſtance. In thoſe of the grain kind, it is always a good practice to arm and eaſe the props, or poſts, which are made uſe of for the purpoſe, with a ſheet of tin, nailed round them, at more than half way up, in ſomewhat the form of an inverted funnel, as this ſerves to ſtop vermin in their progreſs and attempts to get up and into the ſtacks; and tin, on account of its cheapneſs and poliſhed ſurface, is found particularly well ſuited to the purpoſe.

The props or poſts for this uſe ſhould, in all caſes, have ſufficient ſtrength, and be firmly ſet up to or againſt the ſtacks; having a portion of ſtrong thick board laid to the ſtacks, where their upper ends come againſt them, to prevent their entrance into them.

This method is found to ſucceed well in the practice of ſome farmers in Glouceſterſhire, according to the corrected account of the agriculture of that diſtrict.

STACK-*Bars*, a term applied to the large bars or hurdles by which hay-ſtacks in fields are incloſed and ſecured.

The bars and hurdles for incloſing ſtacks ſhould always be of a proper thickneſs and ſtrength, ſo as not to readily give way, but reſiſt any ſtreſs that may be brought againſt them by animals, in getting at the hay, or in any other way. They ſhould alſo be put ſo near together in the fence, as to prevent any hurtful ſort of animal from getting at them.

STACK-*Guard*, a cloth or other covering ſuſpended over ſtacks, during the time of their being built, to protect them from rain, &c. It is applicable both to the ſecuring of corn and hay-ſtacks, as well as thoſe of other kinds. It is uſual for this purpoſe to employ a large ſheet of ſail or other cloth, which anſwers perfectly, and prevents much injury and loſs in wet bad ſeaſons. In the diſtricts of Kent and Surrey, the old or half-worn ſails of ſhips are, according to Mr. Marſhall, made uſe of as guards for ſtacks. But he thinks, that a ſail-cloth, thrown over and immediately upon the hay of a ſtack in full heat, is liable to do more injury, by increaſing the heat, and at the ſame time checking the aſcent of the vapour or ſteam, than ſervice in ſhooting off rain-water.

The improved method of ſpreading the cloth, which he obſerved in the diſtrict of Maidſtone, in the former of the above counties, is, he ſays, this: Two tall poles, uſers, fir-balks, are ſtepped firmly into two cart-wheels, which are laid flat upon the ground at each end of the ſtack, and loaded with ſtones to increaſe their firmneſs. Another pole of the ſame kind, and ſomewhat longer than the ſtack, is furniſhed at each end with an iron ring or hoop, large enough to admit the upright poles, and to paſs freely upon them. Near the head of each of the ſtandards is a pulley, over which a rope is paſſed from the ring, or end of the horizontal pole, by which it is eaſily raiſed or lowered, to ſuit the given height of the ſtack. In the inſtance obſerved, the rick was begun with two loads of hay; yet even theſe two loads were as ſecurely guarded from rain, until more could be got ready, as if they had been houſed: for a cloth being thrown over the horizontal pole, and its lower margins loaded with weights, a complete roof is formed, and exactly fitted to the ſtack, whether it be high or low, wide or narrow; the eaves being always adjuſted to the wall-plate, or upper part of the ſtem of the ſtack, thus effectually ſhooting off rain-water, while the internal moiſture, or ſteam ariſing from the fermentation of the hay, eſcapes freely at either end, as the wind may happen to blow. And what renders this ingenious contrivance the more valuable is, its being readily put up or taken away. The poles, being light, are eaſily moved from ſtack to ſtack, or laid up for another ſeaſon; and the wheels are as readily removed, or returned to their axles. On theſe hints ſir Joſeph Banks ſeems to have made a conſiderable improvement, which is equally ſimple, cheap, and eaſy in the execution; and, at the ſame time, perfectly calculated for the purpoſe.

This improved apparatus, as given by a writer in the tenth volume of the Annals of Agriculture, is thus deſcribed. There are two long upright poſts, poles, or balks of wood, which are firmly fixed and ſet into two wheels, ſomewhat in the ſame manner as the above; one of which is placed at each end of the ſtack, to which ropes and a block-tackle are ſo attached as to be capable of ſuſpending the cloth or ſheet over the ſtack in ſuch a way as to render it readily raiſed or depreſſed at pleaſure, without difficulty or much trouble; the middle part of the cloth being well prepared and ſecured, in order that the hooks of the tackle for regulating it may be attached to it in a ſuitable manner. There are three ropes on each ſide of each poſt or pole, which are faſtened to rings in the upper and top parts of them, and fixed by ſtrong large pegs down to the ground, by which means the upright poſts or poles are held ſteady and firmly in their places. The block-tackle, by which the cloth is rendered capable of being raiſed or let down, as there may be occaſion, conſiſts of an upper and larger, and of a lower and ſmaller block, which anſwer the purpoſe very effectually. There are alſo four pieces, or more, of ropes, which are attached by rings to the bottom parts or edges of the cloth, on each ſide, by which they fix it to the ground or ſtack, by means of pegs driven firmly into them. The whole of the apparatus is ſo contrived, as to be eaſily and readily taken down and removed, as there may be occaſion; and when not wanted, it takes up but little room in a dry ſecure place.

STACK *Hay-Rod*, the ſtrong or ſtout iron rod of the bolt kind, which is forced into hay-ſtacks, in order to make way and form a paſſage for an iron gun ram-rod, which has a ſtrong worm or ſcrew at the lower end of it. In this way a ſample of the hay is ſcrewed and forced or taken out, and the ſtate or condition of the ſtack diſcovered and determined. This neat and uſeful diſcovery and contrivance was made by the late Mr. Ducket, the ingenious farmer at Eſher, in the county of Surrey; and the method practiſed by him, not only for aſcertaining the ſtate of the heat in hay-ſtacks, and preventing its proceeding to too great a degree, but for ſhewing the colour of the hay in them. When the heat is too great, it ſerves alſo for making holes in different parts and places of the ſtacks, in order to let it paſs off, and to admit air more freely, ſo that the hay may be prevented from being injured in any way by it. This is an invention which, of courſe, may be beneficial to the hay-farmer in many different ways.

Stack-*Tackle*, any ſort of tackle or contrivance employed about a ſtack of any kind, either for the purpoſe of aſſiſting and expediting the work of forming, preparing, and building it, or for protecting and ſecuring the materials of which it is compoſed, while the ſtack is forming and finiſhing. Theſe different kinds of tackles and contrivances are often very neceſſary about ſtacks, while the work of forming and finiſhing them is in hand and going on with; as they may ſave much time, labour, and trouble, as well as be of great utility in preſerving the different ſorts of articles in a ſafe ſtate from the effects of the weather, or other cauſes. Every kind of tackle, or contrivance of this nature, ſhould always be made as readily applicable and convenient as poſſible, and ſo that it may perform its intended uſe in the eaſieſt and moſt ready and complete manner there is a capability of, without having any ſort of complexity or difficulty in making uſe of it.

Stack *Hay-Barn*, that ſort of open barn which is contrived for the purpoſe of receiving and having hay ſtacked up in it, in contradiſtinction to thoſe of the cloſe common kind in which it is ſometimes put. Theſe barns are conſtructed in ſeveral different manners, as the nature of the materials may allow, but moſtly on poſts of oak, or ſome other durable kinds, with open frames, ſo as to admit air in a very free manner. They have not unfrequently a capacity of holding from thirty to fifty loads of hay, and, in ſome inſtances, even ſo many as a hundred loads. See Hay-*Barn*.

The queſtion has not yet been fully decided, whether hay keeps better when ſtacked up in the open air, or in common barns, and thoſe formed expreſsly for the purpoſe. The opinion of moſt of the beſt hay-farmers in the ſouthern parts of the kingdom is directly in favour of the open ſtack manner, ſo far as the quality of the hay is in any way concerned; and there can be no doubt but that the ſtack-barn method, deſcribed above, may be equally or more beneficial in that way, and ſtill more advantageous in other reſpects. But how far the cloſe common barn is ſuited to the purpoſe of containing hay, has probably not yet been fully ſhewn. However, in many of the more northern parts of the country, hay is not unfrequently ſecured in barns of this kind, and, on examination, has been found to be equally ſweet and good as when preſerved in ſtacks in the open air. The experimental trials of others, in the more ſouthern diſtricts, have likewiſe ſhewn the ſame thing, ſo far as they have gone; it being found, on cutting and binding up, that it was not leſs good than that from the ſtack-yard, being equally free from duſt. It cannot, however, be diſputed, that hay put up in cloſe barns is, in general, more liable to become duſty, and of a mouldy fuſty quality about the ſides next the walls, and other ſuch parts, than ſuch as is contained in ſtacks in the open air, or in ſuch barns as the above.

Many other ſorts of buildings and roofed contrivances, beſides thoſe of the large ſtack hay-barn kind, may be had recourſe to for containing hay, in different ſituations and circumſtances, and be formed and raiſed in a much more ready and cheap manner.

Stack-*Roofed Corn-Barn*, that ſort of barn which has the roof formed for the fully ſecuring of the ſtacks of grain, or other ſuch matters as may be put into it, and the ſides and other parts ſo raiſed and made open, as to produce perfect ſecurity from vermin, and full ventilation of the contained materials. In the conſtruction of it, upon the low timber platform, which is put on poſts or pillars, as in ſtaddles for grain, the frame or ſkeleton of a perfect barn is raiſed, with ends, ſides, and roof. The ſides and ends are left open for the full admiſſion of air; but upon the roof is put a complete and ſubſtantial coat of thatch, or ſome other ſuitable, light, ſafe material, which being expoſed to no injuries or miſchief from mice, rats, or any thing elſe, excepting fire and the inclemency of the weather, will laſt, it is ſaid, for upwards of thirty years.

This is conſidered by Mr. Howlett, in the corrected account of the ſtate of agriculture in the county of Eſſex, as a very great improvement on the ſtaddle erections for corn-ſtacks or ricks; for though it is remarked, that the pillars and frame in that mode, together with the care and time employed in raiſing and providing them, and in thatching the ſtacks, muſt obviouſly be attended with conſiderable charge beyond what would have been neceſſary for the mere laying up the corn in the common barn; and, after all, it muſt be again taken down and removed, before it can be threſhed;—the height from the ground ſecures it from vermin; the thatch preſerves it from the weather; and the expoſure of its ends and ſides to the air, which are merely the butt-ends of the ſheaves, keeps it entirely ſweet and pure, far beyond the beſt common barn or granary in the world. And, indeed, the farmers' ricks and barns are, it is ſuppoſed, the only kind of granaries which a wiſe and patriotic government in this country will ever encourage: their contents will generally be brought forth at the propereſt time, not ſtinking and ſpoiled by conveyance in ſhips from abroad, or by lying and rotting in the warehouſe of the merchant, but pure, ſound, and good, as when carted from the field.

The ſuperior advantages of this ſtack-roofed mode over that of the common barn, and the common rick or ſtack manner, are, however, it is thought, great and numerous.

Theſe ſorts of barns are often made from fifty to ſixty feet in length, having a breadth or width of ſixteen or eighteen feet; but they may have ſmaller dimenſions, as may be neceſſary. They are ſometimes raiſed on large ſcales, and ſo contrived as to ſerve as cart-lodges for loaded corn, and other ways, upon the moveable rafters on the ſides being taken away. See Staddle, *Grain* Stand, and Wheat *Rick Stand*.

Stack-*Yard*, the incloſure or yard in which the ſtacks of hay and grain, as well as thoſe of other field produce, are placed. Theſe yards ſhould always be conveniently ſituated for the barns or threſhing-mills. They ſhould alſo always be ſufficiently ſpacious and airy, having a firm dry bottom. and ſome adviſe them to be ridged up, to prevent the accumulation of ſurface-water; as by theſe being pretty well raiſed in the middle, and covering the places where the ſtacks are to be built, either with rough ſtones, with a mixture of gravel, or paving them in the ſame manner as ſtreets, much advantage would be gained at little expence. But a much better method is to have the bottom parts for the ſtacks raiſed conſiderably above the ſurface, and placed upon pillars of wood or ſtone, with a covering of wood or ſtone round the circumference, and beams laid acroſs. The incloſing of ſtack-yards is alſo a matter that ſhould be attended to more particularly, and be well performed in ſome manner or other, either by means of low walls or palings.

On large arable farms the ſtack-yards are not unfrequently divided for different ſorts of produce; but this is ſeldom or ever neceſſary for thoſe of the middling or ſmaller ſizes, as it creates an additional expence and trouble, without any adequate advantage being derived from it, eſpecially where the yards, in theſe caſes, are ſufficiently extenſive for the quantity of corn-ſtacks which are to be put into them.

In theſe yards the ſtacks ſhould be arranged ſomewhat according to the nature of the matters or produce which are put into them: thoſe which require to be kept the moſt dry and ſweet, as the grain, pulſe, and hay kinds, in the higher and more open airy parts; and thoſe of the contrary kind in the lower and more confined parts.

Stack *of Wood*, among *Huſbandmen*, is a pile of wood three feet long, as many broad, and twelve feet high.

STACKHOUSIA, in *Botany*, received that appellation from the writer of the preſent article, in honour of John Stackhouſe, eſq. F.L.S. of Pendarvis, in Cornwall, author of a ſplendid work on ſubmarine plants, entitled *Nereis Britannica*, and of ſome botanical illuſtrations of Theophraſtus.—Sm. Tr. of Linn. Soc. v. 4. 218. Brown Bot. of Terra Auſtralis, 23.—Claſs and order, *Pentandria Trigynia*. Nat. Ord. *Terebintaceæ*, Juſſ.? Sm. *Stackhouſeæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-ſhaped, divided half way down into five equal, acute ſegments, permanent. *Cor.* Petals five, equal, inſerted into the calyx, linear-lanceolate, cohering by their claws in the form of a tube much longer than the calyx, their borders narrow, ſpreading horizontally, ſhorter than the tube. *Stam.* Filaments five, thread-ſhaped, unequal, inſerted into the calyx; anthers roundiſh, concealed within the corolla. *Piſt.* Germen ſuperior, three-lobed; ſtyles three, ſhort; ſtigmas obtuſe, ſimple. *Peric.* Capſule of three roundiſh, coriaceous, corrugated cells, each of one valve, not burſting. *Seeds* ſolitary, nearly globular, attached to the permanent central column.

Eſſ. Ch. Calyx in five ſegments. Petals five, connected by their claws. Capſule of three lobes and three cells, not burſting. Seeds ſolitary.

Obſ. The ſtyles, as well as the cells of the capſule, are ſometimes two only.

1. S. *viminea*. Slender Stackhouſia.—Gathered near Port Jackſon, New South Wales, by John White, M.D. to whom we are obliged for ſpecimens. The *root* is tapering, whether annual or perennial we know not. *Stems* ſeveral, erect, twelve or eighteen inches high, ſimple or branched, round, leafy, ſtriated, ſmooth. *Leaves* ſcattered, ſeſſile, ſlightly ſpreading, elliptic-lanceolate, or oblong, obtuſe, entire, ſmooth, rather fleſhy, and ſomewhat glaucous, ſingle-ribbed, an inch or more in length, tapering at the baſe. *Cluſters* terminal, elongated, erect, many-flowered. *Flowers* ſmall, yellowiſh, in little diſtant tufts, two or three together, on ſhort partial ſtalks, with minute bracteas at their baſe. *Capſule* of three rugged lobes, each the ſize of a muſtard-ſeed, ſubtended by the permanent expanded calyx. The flowers bear a reſemblance to ſome ſpecies of *Struthiola* or *Daphne*, but are very different when examined.

This is the only ſpecies that has fallen in our way. Mr. Brown probably may have ſeen more. This learned botaniſt conſiders *Stackhouſia*, "and an unpubliſhed genus, exactly agreeing with it in flower, but remarkably different in fruit," as forming a ſmall natural order, ſufficiently diſtinct from all hitherto eſtabliſhed. He places it between his *Celaſtrinæ* and *Euphorbiaceæ*, "to both of which, but eſpecially to the former, it ſeems to be related in a certain degree." Mr. Brown thus defines the order in queſtion.

Stackhouseæ. *Calyx* of one leaf, in five equal ſegments, with a ſwelling tube. *Petals* five, equal, inſerted into the top of the tube; their claws cohering in a tubular form, longer than the calyx. Their borders narrow, ſpreading like a ſtar. *Stamens* five, diſtinct, unequal (two alternate ones being the ſhorteſt) inſerted into the throat of the calyx. *Germen* diſtinct, of from three to five ſeparate ſingle-ſeeded lobes, the ſeeds erect. *Styles* three to five, ſometimes cohering at their baſe. *Stigmas* undivided. *Seed-veſſel* of three to five lobes, each without valves, ſometimes winged; the central column permanent. *Embryo* erect, central, almoſt as long as the fleſhy albumen.

The plants of this order are herbaceous, with ſimple, entire, ſcattered, ſometimes minute, *leaves*, and lateral, extremely minute, *ſtipulas*. *Spikes* terminal, with three *bracteas* to each *flower*. "The *Stackhouſeæ* are peculiar to Terra Auſtralis, and though found chiefly in its principal parallel, extend more ſparingly both to the ſouthern extremity of Van Diemen's iſland, and to the north coaſt of New Holland."

STACKING, in *Agriculture*, the art and manner of forming, building, and making all ſorts of ſtacks with any kind of farm produce.

In forming, building, or ſtacking any ſort of material of the farm kind, it is moſtly proper to begin in the middle of the ſtaddles or ſtands on which they are to be raiſed, ſo as to form and lay it out to the ſides, ends, or other parts, in a very ſlightly inclining manner, the ear-parts the higheſt in corn or other ſimilar matters, keeping ſuch middle part always well up, and the outſide parts on the ſides, or in other ways, in a conſtantly very gradual, but ſcarcely perceptible, outwardly ſwelling or overhanging manner, proceeding courſe after courſe, in the ſame way, until the top of the ſtem or ſhaft part of the ſtack be reached, from which, in forming the top part, it is to be taken or drawn in, in placing the different courſes of the ſubſtances in nearly the ſame eaſy, gradual, though in rather a quicker manner, until the ridge or top be arrived at; always carefully keeping up the middle, as in the ſtem or ſhaft part. The top or ridge part muſt conſtantly be well and ſafely ſecured; it is ſometimes ornamentally formed. In ſomewhat this way every ſort of ſtack about a farm may be raiſed without any very great difficulty or trouble, if the labourer or perſon who is to form and conſtruct them be but a little converſant with the nature and practice of ſtacking, though he may not be greatly experienced in this ſort of buſineſs. He cannot, however, raiſe or form ſtacks in the very neat, exact, and perfect manner, that complete and profeſſed ſtack-building labourers are capable of performing the work. Nor will he be capable of finiſhing them with the ſame exactneſs, or the ſame degree of neatneſs or elegance. See the next article.

Stacking *of Grain*, the art and practice of building or forming ſtacks of corn, and other ſimilar matters; which is performed in different methods, according to the particular nature and circumſtances of the different caſes. In the execution of this buſineſs, the ſtems of the ſtacks ſhould, however, in general, be ſo formed as to ſwell gradually outwards, quite up to the part termed the eaves, as by this method they are more perfectly ſecured againſt the entrance of moiſture, and at the ſame time require a leſs ſpace to ſtand or reſt upon. And when the building of them is well performed, they have equal ſolidity, and ſtand in as firm and ſafe a manner. But Mr. Marſhall, who has probably not fully conſidered the advantages of this practice, adviſes that the ſtem or body of the ſtack ſhould be carried up as plumb as poſſible, except the laſt courſe of ſheaves, which ſhould project five or ſix inches, to form the eaves: for the weight of the roof will, he thinks, preſs out the upper part of the ſtem ſufficiently. If it overhang in making, its own weight and the weight of the roof will, it is ſuppoſed, ſqueeze it too flat, will ſpoil the appearance of it, and waſte both thatch and time in thatching. The ſtem or body of a ſtack ſhould commonly contain about two-thirds, and the roof one-third of the whole ſtack. If it be built on a frame, the ſtem ſhould, however, contain leſs, and the roof more; if on a bottom, the reverſe. The corners of the ſtem ſhould not be built too ſharp; ſhould be carried up ſnug; by which the ſides will look fuller, and the ſwell given by the preſſure will be more perceptible. The ends of the roof ſhould have a gentle projecture, anſwerable to the ſtem; and the ſides ſhould be carried up rather convex, than flat or concave. Perhaps a roof greatly convex ſhoots off the rains preferably to any other. A corn-ſtack ſhould not, it is ſaid, contain above twenty-one loads, as the riſk of making and getting in is much leſs on a ſmall than on a large ſtack; beſides, a large ſtack does not ſettle ſo true as a ſmall one, and of courſe will not ſtand the weather ſo well. It is true, a large ſtack does not, in proportion, take ſo much thatch and thatching, which are its only advantages.

But in caſes where corn is ſtacked in a looſe manner, it is the uſual practice to have a number of perſons upon the ſtack, the corn being forked up and depoſited on the different ſides all round in a ſimilar method; after this, other parcels are laid all round on the inſide of theſe, ſo as to bind them in a ſecure manner from ſlipping outward; the operator proceeding in the ſame manner till the whole of the middle ſpace is perfectly filled up; when he begins another courſe in the ſame method, and goes on in this mode, with courſe after courſe, till he has raiſed the whole of the ſtem or body part; then he begins to take in for the roof in a very gradual manner, in every ſucceeding courſe, until the whole is brought to a ridge or point, according to the manner the ſtack is formed in. But in order that the roofs may throw off the water in a more perfect and effectual manner, they ſhould be made ſo as to have a ſlight degree of fulneſs or ſwell about the middle of them, and not be made flat, as is too frequently the practice with indifferent builders of ſtacks of this ſort.

The method of proceeding where the corn is bound into ſheaves, is, however, quite different, as there is ſeldom more than one perſon employed in managing the work of building the ſtack, except in caſes where the dimenſions are very conſiderable; in which caſes it is found neceſſary to have a boy to receive the ſheaves from the pitcher, and hand them to the man that builds the ſtack. And in executing the work, it is of the utmoſt importance that the centre of the ſtack be conſtantly kept in a ſomewhat raiſed ſtate above that of the ſides, as by this means the ſheaves have a ſloping direction outwards, by which the entrance of moiſture is more effectually guarded againſt and prevented. And in order to accompliſh this in the moſt perfect method, it is ſaid to be the beſt practice for the workman to begin in the middle of the ſtand or ſtaddle, ſetting the ſheaves together, ſo as that they may incline a little againſt each other, placing the reſt in ſucceſſive rows againſt them, till he comes to the outſide, when he carries a courſe of ſheaves quite round, and in a more ſloping manner than in the preceding courſes. The bottom of the ſtack being formed in this way, it is afterwards uſual to begin at the outſide, and advance with different courſes round the whole, placing each courſe a little within the other, ſo as to bind them in an exact and careful manner, till the ſtacker comes to the middle. And all the different courſes are to be laid on in a ſimilar manner, until the whole of the ſtem is raiſed and completed; when the laſt outſide row of ſheaves is, in moſt caſes, placed a very little more out than the others, in order to form a ſort of projection for the eaves, that the water may be thrown off more effectually. But in caſes where the ſtems of the ſtacks are formed ſo as to project outwards, in the manner already noticed, this may be omitted without any bad conſequences, as the water will be thrown off eaſily without touching the waſte of the ſtack. And the roof is to be formed by placing the ſheaves gradually a little more in and in, in every courſe, until it comes to a ridge or point, according to the form of the ſtack, as has been already obſerved. But in forming and conſtructing this part of the ſtack, great care ſhould conſtantly be taken to give the ear-ends of the ſheaves a ſufficiently ſloping direction upwards, in order that they may be the better ſecured from wetneſs. And to the outſide ſhould be given a rounded form, in the manner that has been already noticed.

In reſpect to the ſtacking of grain, it is obſerved in the Farmer's Magazine, that the corn and its ſtraw muſt neceſſarily be a great deal more dried in the field, to render it proper for being ſecured in barns, than when it is built in ricks, as theſe latter, being expoſed to the free air all round, are by no means ſo apt to heat or mould the grain and ſtraw, as if it were ſtored in common barns. And that, in conſequence of that ſuperior degree of dryneſs neceſſary for barn-harveſting, the grain is certainly a great deal more apt to ſhake out from the ear, in handling and forking into the carts or waggons for being led home. And further, that when built in ricks properly contrived, the grain is likewiſe placed altogether out of the reach of rats and mice, which commit very great waſte in common barns, however well conſtructed; that it is of courſe better that all grain ſhould be built in round ricks in the yard, upon wooden frames open below, raiſed on ſtone ſupports, ſimilar to thoſe on which granaries are fixed. By this plan, it would, it is ſuppoſed, be more effectually ſecured againſt the depredations of vermin; and beſides, the air having free acceſs all round, and even underneath, through the interſtices of the frame, it will be completely prevented from all danger of ſpoiling any way in the rick. And further, that in this way of ſecuring grain, the ricks do not by any means require to be thatched ſo very ſubſtantially, and, of conſequence, expenſively, as is practiſed in general.

Further, it is alſo adviſed, that in building a corn-rick, effectual care be taken to keep the centre or heart of the rick always conſiderably higher than the outer range of ſheaves, as noticed above; ſo that every ſheaf in the rick has a conſiderable ſlope outwards and downwards. When this is properly attended to, and all the ſheaves carefully locked together, and the crown properly put on, the rick will, it is obſerved, turn a very heavy ſhower of rain, even before the thatch is applied. The whole rick, after the thatch is laid on, is finally covered with a net-work of ſtraw-rope, leaving the meſhes about nine or twelve inches wide, all the ends of the ropes being ſecured to a belt-rope, which goes round the rick below the eaves, juſt within reach of a man, and the middle parts of all the ropes are tied to one that goes ſtraight over the top of the rick by ſmall handfuls of ſtraw. See Stack.

And it has been ſtated by the author of "Practical Agriculture," that it is the practice in ſome diſtricts, eſpecially where the ſtacks are made of a circular form, and the weather is wet and unfavourable, to have a funnel or chimney left in them, in order to prevent their taking on too much heat. This is effected by tying a ſheaf up in a very tight manner, and placing it in the middle, on the foundation of the ſtack, pulling it up occaſionally as the building of the ſtack proceeds all round it. And in ſetting up ricks in bad harveſts, it is a practice in ſome places, particularly with barley-crops, to have three or four pretty large poles tied together, by winding ſtraw-ropes round them, ſet up in the middle, round which the ſtacks are then built. But that except the ſtacks are large, or the grain when put into them in an imperfect condition, ſuch openings are quite unneceſſary. Theſe openings in the northern parts of the kingdom are denominated *fawſes*, or *fauſes*: And it is probable that in ſome inſtances they may be prejudicial to the ſtacks, by the admiſſion of too much moiſt air. See HARVESTING *of Grain.*

A curious practice in this mode of ſtacking grain prevails in ſome parts of the northern diſtricts of the kingdom, where the operation is performed round about a high conical frame of wood, which has, in ſome caſes, a ſmall door, provincially termed a *logie*, formed in it on the ſide or quarter from which the wind commonly blows, in order that a more free admiſſion of air may be ſecured, a lateral vent, or ſmall opening, being ſometimes, perhaps, made in the body, a little below the point of the wooden frame, which has in different parts of theſe diſtricts of country the names of *fauſe* houſe and *windy* houſe. The writer of the Corrected Account of the Agriculture of the County of Inverneſs ſuggeſts, that where wood is ſcarce, the ſame effect and advantage may nearly be produced, without an upright timber-frame, by filling a ſack with ſtraw or hay, and fixing a rope to the mouth of it. This ſack is ſet down adjoining to the logie, and in the centre of the ſpace on which the ſtack is to be built; and as the ſtacking advances, the ſack is gradually pulled up, ſo far as is thought neceſſary and uſeful, by which means a future draught of air is freely admitted. Theſe precautions are, however, it is ſaid, moſtly uſed when the material is damp, and the ſtack to be formed on the ground. See STADDLE.

In ſome damp ſituations and moiſt wet ſeaſons, grain is occaſionally ſtacked up in the field in different forms and methods. The writer of the Account of the Huſbandry of Middleſex has remarked, that to the weſtward of the city of Bath, the exceſſive moiſture of the climate has neceſſarily induced and obliged the occupiers of arable land to ſecure their corn or grain crops in the field, immediately after they are bound into ſheaves, by ſtacking them in round ricks or ſtacks, which contain about a cart-load each; the ſheaves being placed in ſuch a manner as to ſecure the ears equally againſt the rain and damp ariſing from the ground. They are ſet on their butt-ends in the bottom parts, but every ſheaf, from the eaves upwards, is placed ſloping in a thatch-like manner, and in the form of a cone. One ſheaf is inverted at the top, and ſpread over this cone-like point; which method ſecures the whole, until it may ſuit the convenience of the farmer to carry the matters to be re-ſtacked, or built up in the barns or ſtack-yards. When theſe ricks or ſtacks are well made or put up, they are ſecure, it is ſaid, againſt every poſſible quantity of rain, and for any reaſonable length of time; even for a whole winter, if it were neceſſary to keep them out ſo long. This is a practice of ſtacking in the field, which, it is thought, deſerves imitation in all wet climates, and indeed in all others, in caſes of wet harveſt ſeaſons.

The method of ſtacking or making the ariſh mow or ſtack, which is another mode of ſtacking grain in the field in ſome of the ſouth-weſtern diſtricts of the kingdom, is thus deſcribed by the writer of the "Weſtern Tour." A ſort of cone or pyramid is firſt formed with ſheaves ſet upon their butt-ends, and in a leaning manner towards their centre; the workman then gets upon them with his knees, an aſſiſtant putting the ſheaves in their proper places before him, while he creeps or crawls round the mow or ſtack, forcing and beating them down in a perfect manner with his knees applied about the binding-place; and continuing in this manner to lay courſe after courſe, until the mow or ſtack be deemed high enough; obſerving to contract the dimenſions of it as it riſes in height, and to ſet the ſheaves more and more upright, until they form at the top a ſharp point, which is capped with an inverted ſheaf, either of corn or reed. In caſes where corn or grain is put up or built in theſe ſtacks, it is moſtly thought to be quite ſafe.

The ſtacking of corn, when carried to the yards, is frequently performed on oblong and other forms of raiſed wood, on frames covered with looſe poles or other matters, ſo as to admit air freely to all parts of the bottoms of the mows or ſtacks, and at the ſame time to prevent rats and other ſuch animals getting into them.

The ſtacking of grain is moſtly performed in a neat and exact manner in many diſtricts towards the middle and more northern parts of the kingdom; but in many of the more ſouthern and eaſtern counties, it is often done in an extremely bad and ſlovenly manner. In Oxfordſhire and Berkſhire ſtacks are formed with peculiar neatneſs, and have much merit in their different forms and ſhapes, being not unfrequently duly arranged, and placed in neat clean ſtack-yards. In the latter of the above counties, it has been remarked, that a farmer who was negligent in theſe reſpects, would be the object of obſervation and deriſion in his neighbourhood. And that the labourer who can make a handſome rick or ſtack, prides himſelf on his ſkill; and as good as well as bad examples are catching, others, in imitation, endeavour to gain credit by the ſame means.

In finiſhing the ſtacking of grain in many places, the ſtem or body parts of the ſtacks or mows are neatly pared round, in order to prevent the vermin, which might leap againſt them, from finding any thing to hold by; and the whole is completed in a neat and exact manner.

STACKING *of Hay*, the work or buſineſs of putting hay up into ricks or ſtacks. This is an art which requires much care and attention in the perſon employed for the purpoſe, though much leſs than that of building corn-ſtacks. There ſhould conſtantly, though it is often too much neglected, be a proper ſtand or foundation, ſomewhat raiſed by wood or other materials, prepared for placing the ſtacks upon; but nothing of the ſhelving outward direction or of the coping kind is here neceſſary. See STACK, STADDLE, and STAND.

It may be noticed, that in performing the buſineſs of ſtacking hay, the work ſhould conſtantly be performed as much as poſſible while the ſun is upon the hay, as much advantage is thus gained in the quality of the hay: and it is neceſſary to have a ſtacker that has been accuſtomed to the buſineſs, and a proper number of perſons to help upon the ſtack, in order that it may be well ſpread out and trodden down. The building of theſe ſorts of ſtacks ſhould be conducted much in the ſame way as thoſe of the grain kind; the middle of the ſtack being always well kept up, a little higher than the ſides, and the ſides and ends be well bound in by the proper application of the ſucceſſive portions of hay as the work advances; and during which it is a good way, where there are plenty of hands, to have the ſides and ends properly pulled into form, as by this means much after-labour is prevented. It is likewiſe of advantage, that the hay ſhould be well ſhaken and broken from the lumps during the operation of ſtacking. The form in which the ſtacks are built is not, as has been already ſeen in ſpeaking of ſtacks, of much conſequence. See STACK.

With the intention of preventing too much heat, ſometimes in building theſe ſtacks, as well as thoſe of the grain kind, holes, pipes, and chimnies are left in the middle, that the exceſſive heat may be diſcharged. But there is often injury ſuſtained by them, from their attracting too much moiſture. See HAY, and HAY-*making*.

For this purpoſe, ſquare ſpouts or troughs, bored full of large holes, and two oppoſite boards, ſecured about nine inches apart, by nailing ſhort laths on them, are ſometimes employed; as well as the drawing up the middle of the ſtacks, while they are building, a baſket or a ſack full of hay, ſtraw, or other ſimilar materials. And in ſome caſes, on the ſtacks heating too much, ſquare openings are cut from the tops to the bottoms of them.

In ſtacking of hay, the uſe of ſalt has likewiſe been found to have the valuable property of keeping it from heating too much in ſuch ſituations, and, by that means, preſerving it of a finer green colour than would otherwiſe be the caſe. Its diſpoſition to counteract or prevent heat is ſo great, it is ſaid, in ſuch caſes, as to render it particularly ſuitable, proper, and valuable in every inſtance where it may be ſuſpected that the hay has been put together without being ſufficiently made.

The hard benty hay of poor uplands may moſtly be ſtacked up without any riſk or danger of heating too much; but that which is of a more open ſucculent nature and quality, on rich or highly manured lands, is for the moſt part very liable to take on too great a degree of heat, and ſhould conſequently be longer delayed in ſtacking, as well as put up in ſmaller quantities together, in order to avoid being injured by being burnt in the mow or ſtack.

The hay of clover, tare, ſaintfoin, and ſome other ſimilar kinds of graſſes, are commonly more diſpoſed to heat in too great a degree than almoſt any other ſorts when put up in ſtacks, not only on account of their being more ſucculent and ſappy, but in conſequence of their nature requiring that they ſhould be a good deal leſs made, in order to preſerve their foliage as perfectly as poſſible. In ſtacking them, therefore, theſe circumſtances ſhould be carefully attended to and kept in mind, and ſmaller, as well as more looſely formed ſtacks of them raiſed. In the county of Middleſex alſo, many farmers are ſaid to make uſe of ſalt, in ſuch caſes, with very good effect, in keeping down the heat.

Where there are great quantities of hay ready on hand at the ſame time, it is of much conſequence that it ſhould all be ſtacked up as ſoon as ever it is fully made, which, though difficult to be accompliſhed in many caſes, ſhould ſeldom be neglected, as its weight and good quality greatly depend upon it, there being every moment from that time a loſs in the weight, as well as the nutritious properties of it, by what is forced off by heat into the atmoſphere. The difference of even a few hours in very hot ſeaſons, may, it is ſuppoſed, be the cauſe of a loſs of fifteen or twenty *per centum* on the hay, by its having been carried beyond the point of perfection in making; and not unfrequently a much greater loſs is ſuſtained. The ſtacking, therefore, in ſuch circumſtances, ſhould always be done as expeditiouſly as poſſible.

In regard to the loſs of the materials before and after they have been ſtacked up, it has been ſuppoſed by the writer of the Middleſex Agricultural Report, that four hundred weight of graſs waſtes in forming into hay, three hundred before it is ready for ſtacking; it is then further reduced by heat and evaporation, in about the ſpace of a month, to perhaps ninety-five pounds; that at between that and ninety, it is apprehended it continues throughout the winter. That from about the beginning of ſpring until the commencement of the following autumn, the different operations of truſſing and conveying it away, render it conſiderably lighter, probably to eighty, by expoſing it ſo much to the ſun and wind: that is, ſuch hay as would weigh ninety pounds on being taken from the ſtack, would be reduced to eighty by the time it is diſpoſed of, as in the courſe of twenty-four hours. On ſuch ſtacked hay being kept longer, little or nothing is loſt in the ſucceeding winter: it is nearly obvious, it is thought, that the ſame ſtacked hay will weigh on being diſpoſed of eighty pounds in the ſummer, and ninety in the winter. From this circumſtance, and ſome others which relate to price, the farmer may, it is conceived, determine what ſeaſon of the year is the moſt advantageous and proper for him to diſpoſe of his ſtacked hay: on large hay-farms ſtacked hay is ſometimes kept for four or five years, and there are not unfrequently very large quantities of hay on them in this ſtate.

The ſtacking or mowing of hay is ſometimes performed in large hay-barns conſtructed for the purpoſe, which are found to be extremely uſeful and convenient on many occaſions, as well as to produce conſiderable ſavings in different ways, beſides the ſafety which they afford. See STACK *Hay-Barn*.

After the work of ſtacking the hay has been finiſhed, and the ſtack been properly pulled and topped up, it may be left until it has ſweated, and is become perfectly ſettled, which moſtly takes place in the courſe of a week or two. It is then ready for thatching. See THATCHING *of Stacks*.

It may likewiſe be noticed, that in building the upper parts of theſe, as well as grain and other ſtacks, the uſe of a ſtage often becomes neceſſary, in order that the materials may be pitched more conveniently to the ſtacker, as has been ſeen under the head STACK. See STACKING-*Stage*.

STACKING *of Pulſe Crops*, the art and practice of putting all the ſorts of farm produce, which have pods in the place of ears, up into ſtacks. It is always neceſſary, in building them, to keep the pod parts, as much as poſſible, from being expoſed to the action and effects of the atmoſphere, as they are very liable to be much injured or quite ſpoiled by the influence of much moiſture or wetneſs, whether communicated by the air or in any other manner. It is conſequently proper in ſtacking up theſe different materials, to always let the ſtem or root-ends of the crops have an outward direction and appearance, they being bound inwardly by ſuch wads, ſheaves, or bundles as have but little ſtem or root parts in them, which is moſtly ſufficiently the caſe in all ſuch ſorts of produce. The middle parts of ſuch ſtacks ſhould always be kept well filled up with ſuch materials while building. The ſtem or ſhaft parts may moſtly be carried up in a pretty plumb or upright manner, but if the outward ſide parts are made and carried up ſo as gradually to diverge or project a very little at the top or eave parts, it will be ſo much the better, and the ſtack will be ſo much the ſafer from the danger of the droppings of the rain-water or any other wetneſs that may fall upon it.

It is hardly ever neceſſary to carry up the top parts in conſtructing ſuch ſtacks to any great height, the lower they are indeed the better, provided they are formed in a regular manner, and ſo as to effectually carry off the water that may fall upon them.

The topping-up of ſuch ſorts of ſtacks ſhould never, however, be much delayed, as the ſeed of ſuch kinds of produce readily ſwell, and are apt to become injured by a very little moiſture in ſuch ſituations.

Theſe ſorts of ſtacks, as well as thoſe of other kinds, ſhould always be built upon proper ſtaddles in ſafe yards or other ſituations.

STACKING *and preſerving of Hop-Poles*, the practice and method of piling them up in ſtacks, for the purpoſe of rendering them ſafe and ſecure againſt wind and bad weather; and the means of preparing their bottom parts againſt the injuries they may receive from the earth or ſoil in which they may be placed. See HOP-*Pole*.

In the ſquare manner of ſtacking up hop-poles, the number of from thirty to forty or more are uſually ſet up to each corner ſo as to form it, which ſhould moſtly ſtand eight, ten, or twelve feet apart in each or every direction at the baſe or bottom parts of them, the top parts uniting, or coming as cloſely as poſſible into contact with each other. By this mode of proceeding, a ſort of ſquare inclining pile is formed, while ſufficient openings or ſpaces are produced below and between them, for contributing to render the poles dry, as well as afterwards for preſerving them, as much as poſſible, in that condition, and at the ſame time for letting the wind paſs among them more freely, by which the danger of their being thrown down or overturned is conſiderably leſſened, as in the caſe of ſtacks of the conical or circular form. In conſtructing this, as well as the other form of theſe ſtacks, a few poles are firſt well fixed up, faſtened and ſecured at the top parts, and then ſet out in a firm ſpreading-out manner at the bottoms, ſo as that the proper quantity of poles may afterwards be regularly and gradually laid to them and conſtitute the ſtack.

The means of rendering the parts of hop-poles which are ſet into and come in immediate contact with the mould or ſoil leſs liable to decay and deſtruction than they are in the ordinary mode, is a matter of much conſequence to thoſe engaged in the cultivation of hops. The following proceſs has been recommended by Mr. Vancouver, in the Corrected Account of the Agriculture of the County of Eſſex. Taking into full and due conſideration, it is ſaid, the very important benefits which are derived from coal-tar, in preventing the depredations of marine inſects on plank and timber, it very naturally occurs, that a preparation of the ſame ſubſtance, judiciouſly applied, might not only produce a ſimilar effect on and againſt inſects in the ground, but, by its gradual and regular ſolution there, become matter of food for the nouriſhment of plants; and that this leads to a very important conſideration, as that of how far the application of the ſame material may become ſerviceable, by prolonging the durability of poſts ſet into the ground, and in the like manner for the preſervation of the parts of hop-poles which are put into the earth, to which particular point, it is ſtated as the ſubſtance of a converſation on the ſubject with the earl of Dundonald, who has taken a great lead and intereſt in the invention, manufacture, and introduction of coal-tar into more general uſe, that he recommends the method of preparing the hop-poles with it, which is given below, to all hop planters.

The parts of the ends of the hop-poles which are intended to be ſet or inſerted into the ground or ſoil, ſhould firſt be ſtripped of their bark for the length of about thirty inches. The poles ſhould then be pointed, and ſcorched or burnt, until the ſurface of them, from which the bark has been removed, becomes black, and in ſome ſort charred. The uſual or cuſtomary depth to which poles are ſet and fixed in the ground, will moſtly regulate with exactneſs how much of the pointed ends of the poles ſhould be treated in the above manner. The burnt end of the pole, while hot, ſhould be dipped into thin coal-tar, which ſhould previouſly be made a little warm, in order that the wood may abſorb and take up as much of it as poſſible. There may perhaps, it is ſuppoſed, be an advantage in dipping or putting the pole the whole ſpace of the thirty inches which is ſtripped of the bark, as by that means twelve inches of what is covered and laid over with coal-tar may be above the ſurface of the ground.

After the paying or coating of the poles with the tar has been completed, they are to be put up or ſtacked with their pointed and tarred ends upwards, until they become perfectly and quite ſufficiently dry; after which they are to be dipped in coal-pitch made boiling hot, and then ſet up again in the ſame manner, to remain in that ſtate until the time when they are wanted for uſe. In caſes where the poles are liable to injury at the upper or ſmaller ends, dipping them in the coal-tar might alſo, it is ſuppoſed, probably be of uſe in preventing the ſeparation of the bark, or the harbouring of inſects.

It is of very material conſequence that the coating or tarring of the poles be performed at ſuch a diſtance of time before they are wanted for uſe, as to allow of the whole covering becoming perfectly firm, hard, and dry. And likewiſe that the poles, before they are begun to be coated over with the tar, be in a quite dry condition, as they take up a much greater quantity of tar when in this ſituation, than when much loaded with moiſture, as is too often the caſe.

The practice of burning or charring the bottom ends of hop-poles has alſo been found highly beneficial in preſerving them from decay without the application of either the coal-tar or pitch, in many caſes and ſituations, as well as ſome other methods. See Hop.

It is always proper to have the poles piled up in proper parcels together, or ſet upright againſt ſome ſort of ſupport in the hop-grounds, while they have the binds about them, until they can be diſengaged from them, as well as afterwards, until they can be ſtaked or pointed, prepared in the above manner, and ſet up into ſtacks, inſtead of having them diſperſed all over the ground in a flat manner, as is the too uſual cuſtom, as by ſuch means they will become readily more dry, be a great deal more free from injury, and at the ſame time be rendered more fit for receiving the preparation.

And in extenſive plantations, it might probably be the ſafeſt, cheapeſt, and moſt convenient way, to have open coarſe ſheds with ſecure cheap roofs built for receiving and preſerving them in, they being piled up in them upon low frames or ſtools with long arms or branches for keeping them up. In this manner they would in all probability be more readily, more perfectly, more conveniently, and more advantageouſly ſecured than in any other way; and thereby a great ſaving of poles moſt likely be produced.

Stacking *of Straw and Stubble.* Straw is often ſtacked up when bound in truſſes, as well as when in the looſe ſtate. In the former mode, the different bundles ſhould be ſtacked in as ſtraight a manner as poſſible, in order to be kept for ſale or other particular uſes. In the latter ſtate the ſtacks ſhould be well pulled while they are forming, in order that they may be cloſe and compact. In building the top parts of ſtacks of this nature, they need not be carried to any great height, but be ſo formed as to ſhoot off the water in a perfect manner.

Stacking-*Bands*, or *Belts*, the ropes or bands uſed in thatching ſtacks of different kinds, whether of the ſtraw, hay, or other ſorts.

Stacking-*Stage*, the ſcaffold or platform employed in building ſtacks of corn, hay, and many other ſorts of farm produce.

Stages of theſe kinds are conſtructed in different ways, ſome being fixed together in a ſort of frame, ſo as to be ſet up againſt the ſtack, and ſuited to the height of pitching by a moveable ſtage. Lately this ſort of ſtage has been conſiderably improved, by being ſo contrived as to be capable of being readily taken in pieces and laid by. It is the contrivance of a gentleman in the county of Suffolk, and deſcribed in the Agricultural Survey of that diſtrict. It conſiſts of two parts, one of which is a frame eight feet wide, made of two fir-balks twenty-two feet long, braced together in a parallel poſition, and having ſeveral holes bored in them, about fourteen feet from the ground, for the reception of the hinges of the ſtage; and a hook in each of them, to hang the chains on which are to ſupport the outward edge of the ſtage, and ſerve to raiſe or lower it at pleaſure. The other part is a moveable ſtage eight feet long, and three feet eight inches broad, having a hinge under each end, at the hinder, or edge neareſt the ſtack; one end of the hinges is made like a bolt, to enter the holes in the balks; the ſtage likewiſe has an iron-plate under each end, with a hole in it to receive a hook on the chain. It is added, that in uſing the ſtage it is ſet againſt the ſtack, when it grows ſo high that it is inconvenient to pitch on to it from the buck of an empty waggon. The holes in the balks moſt commonly uſed are fourteen feet from the ground, about the height of a waggon-load of hay. Should the ſtage be fixed lower, it would be of no uſe, not being wanted whilſt a man can conveniently pitch from the buck of a waggon on to a ſtack; and ſhould it be fixed much higher, it would be found too high for a man to pitch on to, when the waggon is nearly empty.

It has been ſuggeſted, that a ſtage like this is not expenſive in the conſtruction, and might be uſed for nailing up weather-boarding, painting, plaſtering of walls, and ſeveral other purpoſes.

STACKPOLE Head, in *Geography*, a cape on the S. coaſt of Wales. N. lat. 51° 42′. W. long. 4° 57′.

STACKS *of Burgh*, rocks near the E. part of Scotland, one mile W. of Duncanſby Head. N. lat. 58° 23′. W. long. 2° 57′.

Stacks *of Duncanſby*, rocks in the North ſea, near the E. coaſt of Scotland; 1½ mile S. from the mouth of Wick river. N. lat. 58° 36′. W. long. 2° 57′.

Stacks *of Hempriggs*, rocks in the North ſea, two miles S. from the mouth of Wick river. N. lat. 58° 21′. W. long. 2° 57′.

STACTE, ϛακτη, in *Pharmacy*, a fatty reſinous liquid matter, of the nature of a liquid myrrh.

This liquor is very odoriferous, and is held very precious; making alone the perfume called by Dioſcorides *ſtacte*, which, he ſays, ſmells finely, though very bitter to the taſte. We have none of it now but what is ſophiſticated; and what the apothecaries call ſtacte, is uſually no more than liquid ſtorax.

STADARSTAD, in *Geography*, a group of buildings, compriſing a church, the habitation of the miniſter, and a few cottages, in Iceland, ſituated in the peninſula terminated by Snæfell's *Syſſel* (which ſee.) This church was the beſt which the travellers to whoſe account we refer had ſeen, except that of Beſſeſtad. It is conſtructed entirely of wood, and has a pretty large gallery. The mountains that riſe behind Stadarſtad are very lofty, and preſent a bold and precipitous front towards the ſea. About ſix miles from Stadarſtad, in the mountains that approach towards the ſea, is a hot ſpring, in a place called Lyſiehouls. The water iſſues from the top of a mount about ten feet high, and fifty yards in diameter, entirely calcareous. The temperature of the ſpring was 96°, and the water had an acidulous taſte. Not far from the mount were great quantities of incruſtations not calcareous, which had evidently been formed by ſome ancient ſprings. About half a mile from the ſpring is a ſtream of lava, that had flown down from the precipices above, and ſpread over the flat plain intervening between the mountains and the ſea. Near Buderſtad, which is one of the trading ſtations of Iceland, and conſiſts of a merchant's houſe, a large wooden ſtorehouſe, a church, and a conſiderable number of cottages, is another mineral water, the taſte of which was ſimilar to that of Lyſiehouls; the temperature was 46°. Mackenzie's Travels in Iceland.

STADDLE, in *Agriculture*, a term applied to the bottom part, or that on which the ſtack or mow of corn, pulſe, ſtraw, hay, or any other ſort of field produce, reſts, and is formed or built. Theſe ſorts of ſtaddles are contrived in many different ways, according to different occaſions and circumſtances; as, in a walled manner, in the wooden frame method, in the ſimple log mode, and ſome others. The two firſt are, however, by far the moſt proper, where grain or pulſe is to be ſtacked upon them; but the laſt may do for ſtraw and hay occaſionally, where better and more perfect methods cannot be adopted or put in practice. The firſt method is expenſive, and therefore not common. See *Corn*-Stand.

A method more commonly adopted by farmers, is that of the wooden frame, reſting upon low ſupporters of the ſtone or other kinds. In many different diſtricts, the ſtaddles, eſpecially for corn, are conſtructed by means of upright ſtones with caps, placed about ſeven feet diſtance from each other, in a circular, ſquare, or ſome other ſuitable form. The upright ſtone, in ſome caſes, is a truncated pyramid, about four feet in length, a foot being allowed to be let into the ground. On the top, which is about four inches in the ſquare, is placed the cap, which is a round ſtone, flat and ſmooth on the under ſide, and a little convex on the upper, two feet in diameter, and projecting ten inches from every ſide of the upright ſtone. Upon theſe ſtones ſtrong timbers are framed, firſt extending in a croſswiſe direction, and then all around the ſides; a ſtone and cap being, for the moſt part, put in the centre, to take off the bearing of the croſs-timbers. This is a plan of ſtaddle, which, it is thought by many, effectually ſecures the grain againſt rats and other ſimilar ſorts of vermin.

In other ſituations, ſtone or wooden pillars are put down, at proper diſtances from each other, into the ground, upon which is laid a firm and ſtrong ſubſtantial timber-frame, well compacted and put together, of joiſts, beams, and other parts, as may be found neceſſary and expedient. If the ſupporting pillars be of ſtone, they are uſually of a conical form, with ſtone caps faced upon their tops, as above; but if of wood, they are caſed with tin, ten, twelve, or more inches near their upper ends. In the former caſe, the ſtone caps, and, in the latter, the tin coverings, effectually prevent, it is ſuppoſed, the rats and mice from climbing up into the ſtacks.

In ſome of the more northern diſtricts of the country, the corn-ſtacks are occaſionally ſet ſomewhat in the form and manner of little houſes, upon pillars, or arches turned in maſonry, round or on one or more of the moſt expoſed ſides of the ſtraw-yards, where the outlying or other cattle are to be foddered and kept. Where the pillar mode is adopted, a ſtrong ſolid wall, built in maſon work, moſtly forms the outſide, and the pillars are ſet round or on the inſides of the ſtraw-yards. Beams of a proper ſize and length are firſt laid from one pillar to another, and then rafters are laid acroſs from the outſide wall to the pillars and beams, ſo as to form a ſort of flooring; upon which the ſtacks are built of any length and height that may be neceſſary; their roofs being always well ſecured. In the turned arch manner, no pillars or frames of wood are at all neceſſary, the top parts of the arches forming the baſes or ſtaddles for raiſing the ſtacks upon, while the openings of them, or arches below, form the ſtalls for the cattle. In both theſe ways the cattle are well protected below or underneath the ſtacks; the grain is perfectly preſerved from the effects of dampneſs and vermin, by being ſo much elevated; and to the farmer there is a conſiderable ſaving of manure in different ways.

In other caſes, corn-ſtacks are built round and againſt a frame of wood, ſet up firmly in ſomewhat a conical ſhape or manner; the tops of the rafters or boards, of which this ſort of ſtaddle is compoſed, reſting or inclining againſt each other, and reaching ſomewhat above the eaves of the ſtack. This is a kind of ſtaddle which is ſuppoſed to afford much air and ventilation in moiſt damp ſituations, for drying the grain in the ſtacks. See STACKING *of Grain.*

Where the ſimple log manner of forming ſtaddles is in uſe, any ſort of rough large pieces of wood, of the tree or other kind, are laid round the outſides, in the form in which the ſtacks are to be made; in the inſide and middle of which, bottoms or foundations are formed with common wood faggots, buſhes, or any other ſimilar matters; the whole being then well covered with rough ſtraw or haulm of any ſort. See STACKING *of Hay*, and STAND, *Grain.*

The term *ſtaddle*, likewiſe, ſometimes ſignifies a tree, which is ſuffered to grow for coarſe or common purpoſes; as the forming and making of poſts, rails, and other ſimilar uſes.

STADDLE *of Hay*, a term applied to a plot or portion of hay thrown abroad in making. See HAY-*Making.*

STADDLE-*Roof*, any ſort of roof or covering which is placed over ſtaddles, and employed for the purpoſe of protecting or ſecuring the ſtacks of either corn or hay, or of any other ſorts of materials which are built upon them. Staddle-roofs are of many different kinds, and their heights and ſizes are various, according to thoſe of the ſtaddles over which they are laid.

In the county of Devon, a mode of this kind of roof prevails for the ſecuring of corn, in ſome parts of the South-hams in that diſtrict, which appears to be entitled to the conſideration of the farmer.

It is ſaid to have been borrowed from the Dutch, as it is much uſed in Holland, and all the low countries upon the borders of the Rhine and Scheldt rivers. It is likewiſe ſtated to be almoſt univerſally had recourſe to throughout the eaſtern and middle ſtates of North America. And it probably exiſts in different other countries and diſtricts.

It conſiſts of a light moveable roof, formed of ſome ſort of ſuitable and convenient materials for the purpoſe, which is capable of being raiſed or let down at pleaſure over the ſtaddle upon which the ſtack is built. The methods of forming and managing the arrangement of it are theſe. At the diſtance of about four feet from the corners of the ſtaddle or ſtack-frame, are ſunk four ſtrong boxes, well rammed and ſecured in the ground, and of ſufficient capacity to receive about three feet in length of a large pole or ſpar, rounded from a ſquare of ſix inches, being made a little tapering towards the top, and thirty feet in length: on the upper end of this ſpar or pole is fixed a ſtout ring or ferrule, from which is projected a ſtrong iron hook: the four poſts or poles thus formed and fitted up are placed in the boxes at the different corners of the ſtaddle. A two-ſheave tackle is then hitched to the hooks at the tops of the poles or poſts, and a one-ſheave tackle to each corner of the roof, reſting upon the ſtaddle, and preſenting at each corner a portable hoop, or collar, to encloſe the different poles or poſts on which it traverſes up and down, keeping all firm, ſteady, tight, and compact together. Theſe four tackles are manned with as many perſons as may be found neceſſary to raiſe or lower the roof, and thus every ſheaf of grain, or any other ſubſtance, which is brought home to be ſtacked under theſe ſtaddle-roofs, is ſaid to be more immediately and better ſecured from future damage, than if they were any otherwiſe placed under cover, or even ſtowed away in a barn or other ſimilar building. This ſtaddle-roof contrivance is ſaid to be denominated a hay-barrack in the ſtate of Pennſylvania, in North America, in which diſtrict they are equally uſed for the purpoſe of protecting hay as well as corn.

It is noticed, that in climates or tracts of country which are frequently liable to ſudden and violent ſtorms, or thunder-ſhowers, during the periods of hay-time and harveſt, theſe ſtaddle-roofs are moſtly found particularly uſeful, proper, and neceſſary for the farmer, in preſerving his crops of theſe kinds in the beſt and readieſt manner.

The looſe ſtaddle-roofs, uſed in ſome ſituations, are moſtly formed of ſome ſort of very light thin boards of different extents, as ten, twelve, or more feet in length, and which are ſometimes bent or curved on one ſide, and hollowed in the middle, in ſomewhat the manner of the pantiles which are uſed in covering buildings, ſo as to hook on to each other and carry off the wet. Roof-boards of this ſort are in uſe on the farms at Winwick, one of the ſeats of the earl of Derby, in Lancaſhire, and found to anſwer the purpoſe very well, and to be particularly ſerviceable in ſhowery or rainy ſeaſons.

Staddle-roofs of the cloth kind are ſometimes employed; the old ſails of ſhips and other ſimilar ſorts of cloth being provided for the purpoſe.

STADDLE-*Stones*, thoſe which are made uſe of in the conſtruction of ſtaddles, eſpecially when they are intended for the purpoſe of corn, in order to keep rats and other ſorts of vermin out of the ſtacks; and alſo for granaries, to keep them from climbing up into them. Various kinds of ſtones are employed in this way, as thoſe of the free-ſtone, the ſlate-ſtone, the lime-ſtone, and different other kinds. See STADDLE.

Staddle-ſtones are moſtly employed alſo for granaries, wherever the primary conſideration of the farmer is the ſecurity of his corn. In theſe caſes, the old method was to have them only put at the corners, while the buildings ſtood upon a frame of wood, but the improved mode is to have them coped all round, in ſomewhat the ſame manner as corn-ſtands, in order that they may be perfectly ſecure againſt the inroads of deſtructive vermin.

For granaries placed on ſtaddle-ſtones, it has been lately ſuggeſted, in order to prevent vermin from getting up the outward ſteps, that ſuch ſteps ſhould be fixed on the inſide of the lower parts of the door, which are to be balanced with weights, ſo that a ſlight effort may be capable of bringing them down on blocks of ſtone, which are to form the firſt ſteps for the purpoſe, ſuch blocks of ſtone being twenty-four feet by fourteen in the clear. The doors, in ſuch caſes, muſt, of courſe, project in ſome degree in being brought forward, ſo as to reach the ground, or come near to it, for the purpoſe of affording a ready and eaſy entrance into the repoſitories.

STADE, in *Geography*, a town of the duchy of Bremen, with a ſtrong fort, on a ſmall river, about a mile from the Elbe; formerly the capital of a county and reſidence of the counts. It is now the ſeat of the regency of the duchies of Bremen and Verden, and alſo of the chancery, chief court of juſtice, and conſiſtory, and contains three churches. Its two burgo-maſters are counſellors of ſtate. It was formerly a place of conſiderable trade, and from the year 1586 to 1612, an Engliſh ſtaple, which was removed to Hamburg. After having undergone ſeveral revolutions and changes of maſters, it was occupied in 1715 by the troops of Brunſwick. In 1757 the fortifications of it were completed; 24 miles W. of Hamburg. N. lat. 53° 42′. E. long. 9° 21′.

STADECKEN, a town of Germany, in the palatinate of the Rhine; 11 miles W. of Oppenheim.

STADELHOFEN, a town of Bavaria, in the biſhopric of Bamberg; 6 miles S.S.W. of Weiſmain.—Alſo, a town of the duchy of Wurzburg; 7 miles S.S.E. of Gemunden.

STADEN, a town of France, in the department of the Lys; 7 miles S.E. of Dixmude.—Alſo, a river of Germany, which runs into the Nidda, 10 miles N. of Francfort on the Maine.—Alſo, a town of Germany; 20 miles N.E. of Francfort on the Maine.

STADIUM, ϛαδιον, an ancient Greek long meaſure, containing one hundred and twenty-five geometrical paces, or ſix hundred and twenty-five Roman feet; correſponding to our furlong.

The word is formed from the Greek ϛασις, *ſtation;* and it is ſaid, on this occaſion, that Hercules, after running ſo far at one breath, ſtood ſtill. The Greeks meaſured all their diſtances by ſtadia, which they call ϛαδιαζειν.

Eight ſtadia make a geometrical or Roman mile; and twenty, according to M. Dacier, a French league; but according to others, eight hundred ſtadia make forty-one and two-thirds of a league.

Guilletiere obſerves, that the ſtadium was only ſix hundred Athenian feet, which amount to ſix hundred and twenty-five Roman, five hundred and ſixty-ſix French royal feet, or ſix hundred and four Engliſh feet; ſo that the ſtadium ſhould only have been one hundred and thirteen geometrical paces. It muſt be obſerved, however, that the ſtadium was different in different times and places. See MEASURES.

STADIUM was alſo the courſe, or career, in which the Greeks ran their races.

It is ſaid to have derived its name from the meaſure of length mentioned in the preceding article; which being equal to the ſpace of ground allotted for the foot-race, the courſe was from thence called the ſtadium, and the racers were named ſtadieis, or ſtadiodromi. The Eleans, indeed, pretended, that the ſtadium at Olympia was meaſured by the foot of Hercules, which being longer than that of an ordinary man, made their ſtadium longer than any other in the ſame proportion.

Vitruvius deſcribes it as an open ſpace one hundred and twenty-five paces long, terminated at the two extremes with two poſts, called *carcer* and *meta*.

Along it was built a kind of amphitheatre, where the ſpectators were placed to ſee the athletæ exerciſe running, wreſtling, &c.

Pauſanias (lib. vi.) informs us, that the Olympic ſtadium was a terrace compoſed of earth; on one ſide of which was the ſeat of the Hellenodicks, or Hellenodics (ſee HELLENODICÆ), and over-againſt them on the other, was an altar of white marble, upon which the prieſteſs of Ceres Chamyne, and ſome virgins, had the privilege to ſit and view the games. At the farther end of the ſtadium was the barrier, whence thoſe who ran the ſimple foot-race began their courſe; and there, according to the tradition of the Eleans, was the tomb of Endymion.

According to the deſcription given by Wheeler, in his travels, of the remains of the ſtadium at Athens, which was built by Herodes Atticus, it appears to have been a long place, with two parallel ſides, cloſed up circularly at the eaſt end, and open towards the other end, and about one hundred and twenty-five geometrical paces long, and twenty-ſix or twenty-ſeven broad, which gave it the name of a ſtadium.

Though the Olympic ſtadium does not ſeem to have been ſo ſplendid as this at Athens, or another at Delphi, built likewiſe of marble by the ſame magnificent citizen of Athens, yet we may ſuppoſe they were all formed upon the ſame model, as they were deſtined to the ſame uſe. In the ſtadium were exhibited thoſe games which are properly called gymnaſtic. At either end of the courſe ſtood a pillar, the one conſtituting the barrier where the race began, and the other the goal, where the ſimple foot-race, inſtituted or revived by Iphitus, ended.

In the fourteenth Olympiad was added the *diaulos*, or double ſtadium; and the *diaulodromoi*, who ran this race, turned round the pillar erected for that purpoſe at the end of the ſtadium, and returned to the barrier, where their race terminated. But the *dolichodromoi*, or runners in the race called *dolichos*, or the long courſe, which was introduced in the fifteenth Olympiad, and which conſiſted of ſeven, or twelve, or even of twenty-four ſtadia, when they came to the barrier, turned again round the pillar erected at that end, in order to continue their courſe, which required many doublings of the ſtadium.

The ſtadium, or race-ground, called the Olympian *hippodrome*, conſiſted of two parts; the firſt reſembled in ſhape the prow of a ſhip, and was called the *barrier*. In this place were the ſtands for the horſes and chariots, and here they were matched and prepared for the courſe. The next partition was the *liſts*, or the ſpot on which the races were to be run. At the end of the courſe ſtood a pillar, which was the goal, round which the candidates were to turn; and that rider or driver who could make the narroweſt turn and approach neareſt to it, had the faireſt chance, *cæteris paribus*, of ſurpaſſing his rivals. To this Horace alludes in the expreſſion, *Meta fervidis evitata rotis*. Beyond this goal, there was a figure placed on purpoſe to frighten the horſes, called *Taraxippus*, or the *terrifier of horſes*. It is probable, that ſome tricks were practiſed under the diſguiſe of this figure, to render the victory more difficult, and of courſe more honourable, or to try and prove the reſolution and temper of the horſes. On each ſide of the courſe, from one end to the other, the ſpectators were placed; the moſt advantageous ſtations being aſſigned to the judges of the games, and other diſtinguiſhed perſons. In that place where the horſes ſtood which were to run, a long cable was drawn from one ſide to the other, which ſerved the purpoſe of a barrier; about the middle of the prow already mentioned, an altar was erected, upon which ſtood a brazen eagle with outſtretched wings, and the figure of a brazen dolphin was likewiſe placed at the entrance of it. This laſt was ſo contrived, that when the preſident of the races thought proper to put it in motion, it would aſcend at once to ſuch a height, as to be viſible to all the ſpectators. This eagle was dedicated to Jupiter, the patron god of the Olympic games, as the dolphin was ſacred to Neptune, the ſuppoſed creator of the horſe. In the moment when the eagle ſprang into the air, the dolphin ſunk under ground; and upon this ſignal, the cable was removed, and the horſes advanced from the ſtands into the courſe, where they ſtood ready to ſtart. The ſignal for ſtarting was probably the ſame as in the chariot races, and was given by the ſounding of a trumpet. The ſpace of ground round which the horſes were to run, and the number of times which they were required to run round it, will make their courſe or heat to amount to about four miles, or ſomewhat more. See on this ſubject Weſt's Odes of Pindar, and Preliminary Diſſertation on the Olympic Games, p. 43, &c. p. 84, &c. For other particulars, ſee HIPPODROME.

There were ſtadia likewiſe covered over, and encompaſſed with colonnades and porticoes, ſerving for the ſame exerciſes in bad weather. Captive children uſed to run the ſtadium.

A more natural derivation of the word ſtadium, from

στασις,

ϛασις, *ſtation*, than that popular one mentioned in the laſt article, may be drawn from the athletæ ſtopping and reſting when at the end of this courſe: whence the name might be applied to the ſame diſtance meaſured in any other place.

STADIUS, John, in *Biography*, a German aſtronomer, was born in 1527, and ſtudied at the univerſity of Louvain, where he applied himſelf with ſo much diligence to mathematical purſuits, that he was very ſoon qualified to become a profeſſor; he reſided ſome time at Liege, and was allowed a ſalary by the biſhop, for whom he annually calculated an ephemeris, adapted to the meridian of Antwerp, beginning from the year 1554. The ephemerides of Stadius were much uſed by the celebrated Dutch mathematician Stevin, though they were afterwards proved to be in many reſpects inaccurate. From Louvain, Stadius went to Savoy, with a commiſſion as mathematician to the king of Spain, and he removed thence to Bruges, in Flanders, where he compoſed his "Faſti Romanorum," which were publiſhed by Hubert Goltzius, whoſe daughter was married to his ſon; after this he was invited to France as profeſſor royal of mathematics, and lived there in high reſpect and honour till he became enthuſiaſtically attached to judicial aſtrology, and on the faith of that pretended art he began to predict future events. He died in the year 1579, in the fifty-ſecond year of his age. He is author of ſome aſtrological treatiſes, and tranſlated a work of Hermes Triſmegiſtus, entitled "Jatro-mathematicæ, ad Amonem Ægyptium conſcripta."

STADL, in *Geography*, a town of the duchy of Stiria; 8 miles N.E. of Gratz.

STADLIN, or Stadlau, a town of Sileſia, in the principality of Breſlau, on the Stober; 27 miles E. of Breſlau.

STADLKIRK, a town of Auſtria; 4 miles N. of Steyr.

STADMANIA, in *Botany*, ſo named by Lamarck, in commemoration of a botanical traveller, M. Stadman, to whom he was obliged for the knowledge of the plant.—Lamarck Illuſtr. t. 312. Poiret in Lam. Dict. v. 7. 376.—Claſs and order, *Octandria Monogynia*. Nat. Ord. *Sapindi*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, minute, of one leaf, with five ſhort, oval, rather pointed, teeth. *Cor.* none. *Stam.* Filaments eight, thread-ſhaped, erect, rather longer than the calyx; anthers terminal, roundiſh. *Piſt.* Germen ſuperior, oblong; ſtyle very ſhort; ſtigma triangular. *Peric.* Berry dry, globoſe, generally attended by the rudiments of another abortive one. *Seed* ſolitary, globoſe, large.

Eſſ. Ch. Calyx with five teeth. Corolla none. Stigma nearly ſeſſile. Berry dry, with one ſeed.

1. S. *oppoſitifolia.*—Native of the iſland of Mauritius, where the French call it *Bois de fer*, or Iron-wood, from the hardneſs of the wood, which is employed for many uſeful purpoſes. The half-ripe berries, preſerved in a moiſt form with ſugar, are ſaid to be tolerably good.—The tree is large and handſome, with a tall erect *trunk*, and ſpreading, oppoſite, round *branches*, of a greyiſh hue, downy when young. Poiret deſcribes the *leaves* as ſimple, oppoſite, ſtalked, elliptic-lanceolate, coriaceous, perfectly entire, obtuſe, ſlightly contracted at their baſe, ſmooth; ſhining above; paler and browniſh beneath; their length three or four inches, breadth an inch, or inch and half. *Footſtalks* three lines long. *Flowers* about the ends of the branches, in long, ſtalked *cluſters*, with ſhort, thick, often aggregate, partial ſtalks, having a ſmall tuberculated permanent *bractea* at the baſe of each.—Such is Poiret's account; but Lamarck's plate evidently repreſents the *leaves* as alternate, pinnate, of from three to ſix pair of oppoſite leaflets; the cluſters of *flowers* being axillary. Such we believe to be the true nature of the plant. We have ſpecimens brought by Commerſon from the iſles of Mauritius and Bourbon, and marked *Bois des Gaulettes*, a name which does not occur in Juſſieu, which, if not the ſame ſpecies, have every appearance of belonging to this genus. In theſe the *leaves* are alternate, abruptly pinnate, their common *footſtalks* ſlightly winged. The flowers are in ſhort, denſe, compound, axillary, ſilky cluſters. *Calyx* and *germen* very ſilky. *Fruit* nearly ſmooth, crowned with the permanent *ſtyle* and *ſtigma*. We dare hardly ſuſpect ſo much inaccuracy of deſcription in the authors cited as to take this for their very identical *Stadmania*, but that it belongs to the ſame genus there can ſcarcely be any doubt. We find here and there even the appearance of a bud, or abortive leaflet, at the end of the common *footſtalk*, as repreſented more ſtrongly by Lamarck, which perhaps led Poiret to take the compound leaf for a branch.

STADT-AM-HOF, in *Geography*, a town of Lower Bavaria, on the Danube, oppoſite to Ratiſbon, and connected with it by a bridge. It has two convents and an alms-houſe, to the latter of which Lutherans and Roman Catholics are equally admiſſible; the objects of relief, as well as the governors, being half Lutherans and half Catholics; its yearly revenue is ſaid to amount to 80,000 florins.

STADTBERG, or Marsberg, a town of the duchy of Weſtphalia, on the Dimel; 20 miles S. of Paderborn.

STADTHAGEN, a town of Weſtphalia, in the county of Schauenburg, endowed in the 13th century with conſiderable privileges, and ſurrounded with ditches, ramparts, walls, and towers. From its ſufferings during the 30 years' war, it has not yet recovered. The palace of the prince of Schauenburg-Lippe is in this town, and the gardens have a mineral ſpring; 8 miles E. of Minden. N. lat. 52° 18′. E. long. 9° 20′.

STADTHOLDER, Stadthoulder, or *Stadholder*, a governor or lieutenant of a province, in the United Netherlands, particularly that of Holland, where the word (now indeed almoſt obſolete) has been moſt uſed, by reaſon of the ſuperior importance of the government of that province.

Menage derives the word from *ſtadt*, *ſtate*; and *houlder*, *holding*, *q. d.* lieutenant of the ſtates. Others will have it compounded of *ſtad*, or *ſtede*, *ſtead*, or *place*; and *houlder*, *holding*; in regard this officer held the place of the counts, and repreſented them in their abſence.

The ſtadtholder, *i. e.* the ſtadtholder of Holland, was the firſt member of the republic: he was chief of all the courts of juſtice, and might preſide therein when he pleaſed. All ſentences, judgments, &c. were diſpatched in his name. When an office became vacant in any of the courts, the ſtates propoſed three perſons to the ſtadtholder, who choſe one of them. He even pardoned criminals, which is a ſovereign prerogative: and he had the choice of ſcabines, or chief magiſtrates, in each city; to which end the council of the city always preſented him two perſons, one of whom he appointed.

In ſeveral cities he had the ſame right of nominating the burgo-maſters and counſellors; as at Rotterdam, Dort, &c. He had alſo a power to caſhier the magiſtrates, and put others in their room, when he found it neceſſary for the public good, upon giving a reaſon for the ſame.

By article VI. of the union of Utrecht, the States conſtituted him arbiter of all the differences that might ariſe between the ſtates of the ſeveral provinces, or between the cities and the members of the ſtates of the province.

To the dignity of ſtadtholder was inſeparably annexed that of captain and admiral-general of the province; in which quality he named all the officers, and diſpoſed of all military poſts. He took care of the execution of the ordinances of the ſtates; and his authority gave him a right to receive, and give audience to ambaſſadors from foreign princes, and even to ſend ambaſſadors on his own private affairs.

The office of ſtadtholder was very ancient: the counts, not being able to reſide in Holland, appointed ſtadtholders to command in their abſence in the ſeveral provinces; beſides a governor-general of all the ſeventeen provinces of the Netherlands.

William I., prince of Orange, was made ſtadtholder of Holland and Zealand in 1576, and ſoon after of the provinces of Guelders, Utrecht, and Overyſſel, at the time when the Dutch ſhook off the Spaniſh yoke; which enabled him to contribute greatly to that happy event.

In 1584, when William I. was aſſaſſinated, the ſame dignity was conferred, by the ſame provinces, on his ſon prince Maurice, who was ſucceeded by his brother Frederic-Henry in 1625. Upon his death, in 1647, his ſon, William II., became ſtadtholder, and he poſſeſſed this dignity till his death in 1650. The ambitious views of this prince having given offence to the provinces of the republic, they took meaſures to reduce the authority of the ſtadtholder; and the province of Holland formed a deſign of excluding his ſon, William III. prince of Orange, afterwards king of England, from the dignity poſſeſſed by his anceſtors. However, in 1672, Holland, alarmed at the progreſs of Lewis XIV., declared William ſtadtholder, and captain-general of the forces of the republic, with the ſame power which his predeceſſors had enjoyed. Their example was followed by four other provinces; and, in 1674, on account of his ſignal ſervices to the ſtates of Holland, they declared him hereditary ſtadtholder, and determined that his dignity ſhould deſcend to his male heirs. He was ſucceeded by his appointed heir, the prince of Naſſau-Dietz, hereditary ſtadtholder of the provinces of Frieſland and Groningen, from whom the dignity deſcended to his ſon, William-Charles-Henry-Friſon. In 1722 he was named ſtadtholder by the province of Guelderland.

In 1747, the ſtadtholderſhip was extended to all the ſeven united provinces, and made hereditary in the male and female repreſentatives of the family of Orange. For other particulars reſpecting the change of government, &c. ſee Holland and United Provinces.

STADTKYLL, or Statkyl, in *Geography*, a town of France, in the department of the Roer, on the Kyll; 8 miles N.N.W. of Gerolſtein.

STADTLAND, a ſmall iſland in the North Atlantic ſea, near the coaſt of Norway. N. lat. 62° 10′. E. long. 5° 50′.

STADT-LOEN, a town of Germany, in the biſhopric of Munſter; 23 miles W. of Munſter. N. lat. 52° 6′. E. long. 6° 54′.

STADT-OLDENDORF, a town of the principality of Wolfenbuttel, containing about 200 houſes; 15 miles W.N.W. of Eimbeck.

STADTSBUGDEN, a town of Norway, in the province of Drontheim; 10 miles N.N.W. of Drontheim.

STADT-STEINACH, a town of Bavaria, in the biſhopric of Bamberg; 7 miles N.E. of Culmbach.

STÆBIS, in *Botany*, a name given by the modern Greeks to a plant growing very plentifully in the iſland of Crete, and ſeeming to be the ſame with the *ſtabe* of the ancient Greeks, when uſed as the name of the pheos or hippopheos; for the ancients uſed it alſo as the name of a low plant of the gnaphalium kind, growing in marſhy places, with which they uſed to ſtuff beds, &c.

STÆBIUM, a name given by the modern Greeks to the plant called *hippopheos* by Dioſcorides: that author alſo ſometimes called it *ſtabe*.

STÆBROECK, in *Geography*, a town of Guiana, on the eaſt coaſt of the river Demarari.

STÆCHAS, in *Botany*. See Cassidony.

STÆHELINA, appears to have been a name of Haller's, which Linnæus removed to the preſent genus. There have been ſeveral Swiſs botaniſts, authors of inaugural diſſertations, or other ſmall treatiſes not generally current, of the name of Stæhelin, or Stehelin. Haller ſeems to have intended principally to commemorate his beloved and regretted friend and companion, Benedict Stæhelin, to whom he addreſſes two epiſtles among his poems. (See his *Biblioth. Botanica*, v. 2. 175, and *Hiſt. Stirp. Helvet.* v. 1. 136.) In the latter place he contends that he had given this name to the *Bartſia alpina*, before Linnæus dedicated that genus to his own, no leſs tenderly lamented, friend Bartſch. (See *Fl. Suec.* ed. 2. 211.) However the right of priority may be circumſtanced, the *Bartſia* of Linnæus, like his *Stæhelina*, has prevailed; nor can the warmeſt admirer of Haller or of Stæhelin now regret, that the latter has obtained a moſt elegant and remarkable genus, of the compound tribe; he having particularly written upon that order, in a diſſertation publiſhed at Baſil in 1721, after the diſtinguiſhed example of Vaillant, of whom he had been a favourite diſciple.—Linn. Gen. 415. Schreb. 546. Willd. Sp. Pl. v. 3. 1783. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 512. Sm. Pl. Ic. 71. Prodr. Fl. Græc. Sibth. v. 2. 162. Juſſ. 175. Gærtn. v. 2. 412. (Serratula; Lamarck Illuſtr. t. 666. f. 3, 4.)—Claſs and order, *Syngeneſia Polygamia-æqualis*. Nat. Ord. *Compoſitæ diſcoideæ*, Linn. *Cinarocephalæ*, Juſſ.

Gen. Ch. *Common Calyx* oblong, cylindrical, ſlightly ſwelling, imbricated with lanceolate erect ſcales, each terminated by a ſmall, ſhort, coloured ſcale. *Cor.* compound, uniform, tubular: all the florets equal, perfect, of one funnel-ſhaped petal, whoſe limb is bell-ſhaped, in five equal, acute ſegments. *Stam.* Filaments in each floret five, capillary; anthers united into a cylindrical tube, each of them having two elongated teeth at the baſe. *Piſt.* Germen very ſhort; ſtyle thread-ſhaped; ſtigmas two, oblong, obtuſe, erect. *Peric.* none but the unchanged calyx. *Seeds* ſolitary, oblong, very ſhort, quadrangular: down branched or cloven, longer than the calyx. *Recept.* flat, covered with very ſhort, permanent, chaffy, branched ſcales.

Eſſ. Ch. Receptacle with branched ſcales. Seed-down branched. Anthers with a pair of threads at the baſe. Calyx imbricated, rather ſwelling.

1. S. *dubia*. Roſemary-leaved Stæhelina. Linn. Sp. Pl. 1176. Willd. n. 1. Ait. n. 1. Dickſ. Dr. Pl. n. 13. Gerard Gallopr. 190. t. 6. (Serratula; Lamarck f. 4. Chamæchryſocome prælongis purpuraſcentibuſque Jaceæ capitulis; Barrel. Ic. t. 406. Stœchas citrina altera inodora; Lob. Ic. 486.)—Leaves ſeſſile, linear, ſomewhat toothed; downy and white beneath. Seed-down ſmooth, about twice as long as the nearly cylindrical calyx.—Native of dry open hills and fields, in Spain, Italy, and the ſouth of France. Parkinſon appears to have cultivated it, but we have never met with the plant in any garden, nor does it make a figure even in catalogues. The *ſtem* is ſhrubby, of humble growth, buſhy, with round leafy branches, clothed with cloſe white cottony down; as are alſo the backs of the very narrow, toothed, ſlightly revolute *leaves*, each above an inch long. *Flowers* terminal, erect, either ſolitary or

ſomewhat corymboſe, making a ſingularly elegant appearance, even in dried ſpecimens, on account of their partly downy *calyx*, variegated with roſe-colour and brown, ſurmounted by the tuft of ſilvery *ſeed-down*, intermixed with the long, tubular, crimſon *florets*, which are eight or ten in each calyx. The genus of this ſpecies was conſidered doubtful by Linnæus, becauſe the *ſeed-down* is deſcribed by Gerard as ſimple. It is, however, curiouſly branched from the baſe, which, added to the bearded *anthers*, ſufficiently eſtabliſhes the character, though we have not examined the ſcales of the *receptacle*. The habit, moreover, is well marked, and proves this genus, which ſome French botaniſts have ſcrupled to admit, to be one of the moſt natural, as it unqueſtionably is the moſt elegant, of the ſyngeneſious family in Europe. Willdenow has ſurely altered the ſpecific character for the worſe.

2. S. *arboreſcens*. Storax-leaved Stæhelina. Linn. Mant. 111. Willd. n. 2. Ait. n. 2. Schreb. Dec. t. 1. Sm. Fl. Græc. Sibth. t. 845, unpubliſhed. (Cyanus arboreſcens altera, ſtyracis folio; Alpin. Exot. 33. t. 32. Ciano fruticoſo di Candia; Pon. Bald. 165.) — Leaves ſtalked, elliptical, entire; ſilky beneath.—Native of rocks on the white mountains of Crete, and in the iſles of Hyeres. Miller is ſaid to have cultivated this fine plant, before the hard winter of 1740, which was fatal to ſo many oriental varieties in the Engliſh gardens. The *ſtem* is woody, two feet high, ſometimes an inch in diameter, with round, leafy, ſilky, aſcending branches. *Leaves* remarkably handſome, elliptical or ſomewhat heart-ſhaped, obtuſe, two or three inches long and half as broad; ſmooth and dark-green above; white and beautifully ſilky beneath; with one rib, and many branching veins. *Footſtalks* ſilky, about an inch long. *Flowers* terminal, corymboſe, light purple. *Calyx* ſlightly ſwelling, its ſcales roundiſh-ovate, partly ſilky. *Anthers* with a double feathery beard. *Seed-down* roughiſh, cloven in a finger-like manner, like the ſcales of the *receptacle*.

3. S. *fruticoſa*. Smooth Plantain-leaved Stæhelina. Linn. Syſt. Nat. ed. 12. v. 2. 538. Willd. n. 3. (Centaurea fruticoſa; Linn. Sp. Pl. 1286. Serratula; Lamarck f. 3. Cyanus repens; Lob. Ic. 548.)—Leaves obovato-lanceolate, entire, tapering at the baſe, ſmooth on both ſides.—Native of Crete and the Levant. Dr. Sibthorp mentions having gathered it on rocks in the iſland of Chéro, but no ſpecimens are found in his herbarium. The *ſtem* is ſhrubby, with round, minutely roughiſh, branches. *Leaves* near two inches long, dotted, tapering down into a winged footſtalk. *Flowers* ſaid to be white. *Calyx* nearly cylindrical, with oblong, acute, partly downy ſcales. *Seed-down* rough. Its peculiar ſtructure, or that of the ſcales of the *receptacle*, our ſpecimens will not allow us to aſcertain.

4. S. *haſtata*. Halberd-leaved Stæhelina. Vahl. Symb. v. 1. 70. Willd. n. 4. (Chryſocoma ſpatulata; Forſk. Ægypt.-Arab. 147.) — "Stem ſhrubby. Leaves haſtate, hoary, ſeſſile."—Gathered by Forſkall near Taæs, in Arabia Felix. A low rigid *ſhrub*, with numerous, round, hoary *branches*. *Leaves* not half an inch long, very obtuſe, dilated into an horizontal lobe at each ſide; moſt hoary beneath; tapering at the baſe. *Flowers* ſolitary, ſeſſile, towards the extremities of the branches. *Calyx* at firſt cylindrical, then turbinate, with linear keeled ſcales. *Seeds* villous; *down* ruſty, rather rigid, very finely toothed where it projects beyond the calyx. *Receptacle* ſcarcely chaffy.—Vahl, from whom we borrow this deſcription, as we have ſeen no ſpecimen, might poſſibly not be aware of the true characters of a *Stæhelina*, and therefore might, like Linnæus, Gerard, and others, not obſerve whether the *ſeed-down* were branched in this ſpecies. Its genus therefore remains doubtful.

5. S. *unifloſculoſa*. Simple-flowered Stæhelina. Sm. Prodr. Fl. Græc. Sibth. n. 2016. Fl. Græc. t. 846, unpubliſhed. — Leaves ovate, acute, toothed; downy and ſnow-white beneath. Stem ſomewhat ſhrubby. Calyx ſingle-flowered. — Found on mount Parnaſſus, by Dr. Sibthorp. The *root* of this very pretty ſpecies is ſtrong and woody, bearing numerous, partly decumbent, branched, leafy, hoary, ſhrubby *ſtems*, about a ſpan high. *Leaves* ſtalked, an inch or an inch and half long; ſmooth and dark-green above; very white beneath; their points ſomewhat reflexed. *Flowers* five or ſix at the top of each ſtem, corymboſe, erect, ſmall. *Calyx* cylindrical, brown, ſhining, nearly ſmooth, half an inch long, containing a ſolitary, purple, ſtarry *floret*, with tawny *anthers*, whoſe baſe is furniſhed with a double feathery beard. *Seed-down* cloven in a digitate manner. Nothing can be more certain than the genus of this plant, though its ſingle *floret* forms one of thoſe exceptions in its natural order, which render abſolute definitions, in botany, ſcarcely ever poſſible.

6. S. *ilicifolia*. Holly-leaved Stæhelina. Linn. Suppl. 358. Willd. n. 5. Sm. Plant. Ic. t. 71.—Leaves oppoſite, on ſhort ſtalks, heart-ſhaped, bluntly toothed; ſmooth and ſhining above; woolly beneath. Points of the calyx-ſcales naked. — Native of New Granada, from whence Mutis ſent ſpecimens to Linnæus. The *ſtem* is ſhrubby, or arboreſcent, with round leafy *branches*, downy when young. *Leaves* rather above an inch long, rigid, obtuſe, revolute, coarſely toothed, reticulated with veins; of a ſhining green, as if varniſhed, on the upper ſide; denſely woolly and white beneath; on ſhort, thick, hoary *ſtalks*, remarkable for being oppoſite, thoſe of all the foregoing being alternate. *Stipulas* none. *Panicles* terminal, corymboſe, denſely woolly, with lanceolate woolly *bracteas*. *Calyx* almoſt hemiſpherical, very woolly; its inner ſcales with ſmooth, membranous, fringed, finally inflexed, points. *Florets* numerous, yellow; their limb erect. *Anthers* with two points at the baſe. *Seed-down* rough, or feathery, ſcarcely branched or digitate. Scales of the *receptacle* ſhort, rigid, with two or three teeth.

7. S. *aquifolia*. Kermes-leaved Stæhelina. (Elichryſum arboreſcens, ilicis cocciglandiferæ folio; Plum. Cat. Amer. 9. Ic. 114. t. 123. f. 2.) — Leaves ſcattered, on ſhort ſtalks, roundiſh, abrupt, with ſpinous teeth; ſmooth and ſhining above; woolly beneath. Calyx-ſcales downy throughout. — Gathered in South America by Plumier. This is in many reſpects nearly akin to the laſt, though eſſentially diſtinct. The *leaves* are but half the ſize, with finer veins, and ſharp ſpinous teeth. *Flowers* yellow, ſeſſile, either ſolitary, or ſeveral together, at the leafy ſummit of each branch. *Calyx* longer, and more regularly imbricated, its ſcales lanceolate, finely and uniformly woolly, without any membranous inflexed points. The *anthers* have two briſtly naked points at their baſe, like the preceding, and the *ſeed-down* is rough; we cannot perceive it to be branched. We have not been able to examine the *receptacle*. There cannot be the leaſt doubt of this plant belonging to the ſame genus as the laſt, and the points in which it differs ſpecifically, ſerve to bring it nearer to other *Stæhelinæ*.

8. S. *gnaphalodes*. Soft-linear-leaved Stæhelina. Linn. Sp. Pl. 1176. (Leyſera ſquarroſa; Thunb. Prodr. 160. Willd. Sp. Pl. v. 3. 2133. Jacea æthiopica, ſtœchadis citrinæ majoribus tomentoſis foliis, capitulorum ſpinis et ſquamulis ex aureo colore nitentibus; Pluk. Almageſt. 193. t. 302. f. 3.) — Leaves thread-ſhaped, woolly. Flowers ſolitary, on long ſtalks. Points of the calyx-ſcales reflexed, membranous, naked, acute.—Native of the Cape of Good

Hope, but rare, and as yet a ſtranger in our greenhouſes. The *plant* is ſhrubby, branched, clothed throughout with white cottony down. *Leaves* an inch and a half to three inches long, very narrow, obtuſe, alternate. *Flower-ſtalks* terminal, ſolitary, erect, ſimple, ſingle-flowered, twice as long as the leaves, woolly like them. *Calyx* ovate, of numerous imbricated ſcales, the inner ones gradually longeſt, as in the laſt, all woolly, with ſhining, tawny or brown, membranous edges, and a ſtrongly reflexed, tapering, almoſt pungent, ſmooth point, of the colour and texture of the edges. *Florets* apparently yellow. *Anthers* with two ſlightly feathery points at the baſe. *Seed-down* feathery, divided at the baſe into ſeveral palmate portions, like the ſtamens of a polyadelphous flower. *Scales* of the receptacle crenate, or many-cleft, at the ſummit.—We know not on what grounds this has been referred to *Leyſera*, there being in our ſpecimens no appearance of a radius, nor any thing of the peculiar habit or characters of that genus. But if it were ſo, this, being the original *Stæhelina*, ought not to be changed. The more particular explanation, than heretofore, which we have given of the reſt of the ſpecies, anſwering alſo to this in ſo many peculiar and eſſential characters, will we truſt eſtabliſh the genus before us beyond any poſſibility of doubt. Plukenet's figure of *S. gnaphalodes*, the only one we can find, though rude, is characteriſtic, eſpecially in the points of the calyx.

9. S. *ſpinoſa*. Thorny-leaved Stæhelina. Vahl Symb. v. 1. 69. Willd. n. 6. (Chryſocoma mucronata; Forſk. Ægypt-Arab. 147.)—Leaves nearly cylindrical, ſimple or pinnatifid, with awl-ſhaped ſpinous points. Calyx-ſcales elliptic-lanceolate, erect.—Found by Forſkall in Egypt. The *ſtem* is ſhrubby, buſhy, rigid, with angular branches. *Leaves* alſo rigid, ſlender, like branched thorns, an inch or inch and half long, roughiſh, alternate. *Flowers* terminal, few, ſomewhat corymboſe, yellow, according to Vaillant, who is cited by Vahl. *Calyx* at firſt cylindrical, then ſpreading and turbinate, of many, nearly ſmooth, imbricated, ſtraight ſcales, each tipped with a ſcarcely diſcernible, erect, prickle. *Seeds* hairy, their down very minutely toothed according to Vahl, and the *receptacle* clothed with ſhort briſtly ſcales. We have not ſeen theſe parts, nor the *anthers*, ſo that we cannot be certain of the genus. One of Forſkall's ſpecimens, now before us, has decidedly pinnatifid *leaves*.

10. S. *Chamæpeuce*. Pine-leaved Stæhelina. Linn. Syſt. Nat. ed. 12. v. 2. 538. Willd. n. 7. Ait. n. 3. Sm. Fl. Græc. Sibth. t. 847, unpubliſhed. (Serratula Chamæpeuce; Linn. Sp. Pl. 1147. Chamæpeuce; Alpin. Exot. 77. t. 76. Stebe capitata, overo Chamepino frutticoſo di Candia; Pon. Bald. 75. Jacea fruticans, pini folio; Pluk. Phyt. t. 94. f. 3.)—Leaves linear, crowded, elongated, revolute; downy beneath. Calyx ovate. Scales lanceolate, erect.—Native of rocks in Crete and Cyprus, where, as well as in Greece, and on mount Athos, it was gathered by Dr. Sibthorp. Parkinſon mentions this ſpecies as cultivated here in 1640. It is ſtill preſerved in curious greenhouſes, and may be ſeen at Chelſea, flowering all ſummer long. The *ſtem* is ſhrubby, buſhy, ſtout, two or three feet high, its round cottony *branches* clothed with abundance of long, narrow, drooping, revolute, acute *leaves*; ſmooth and green above; covered with white cottony down beneath; their baſe ſomewhat dilated. *Flowers* forming a ſort of ſpare leafy panicle at the top of each branch, erect. *Calyx* ovate, or nearly globoſe, bigger than a hazel-nut, of numerous, cloſely imbricated, lanceolate, acute, downy, crimſon-pointed ſcales. *Flowers* crimſon. *Anthers* with a pair of ſimple, not feathery, briſtles. *Seeds* poliſhed, obovate, variegated with brown; their *down* the length of the calyx, feathery, but not branched or palmate. Scales of the *receptacle* in many briſtly ſegments.

11. S.? *imbricata*. Imbricated Stæhelina. Berg. Cap. 233. Linn. Mant. 2. 281. Willd. n. 8. Thunb. Prodr. 143.—"Leaves ovate, pointed, imbricated; downy beneath. Calyx turbinate; its inner ſcales with reflexed coloured points.—Native of the Cape of Good Hope. The *ſtem* is ſhrubby, a ſpan high, with cluſtered downy branches. *Leaves* ſeſſile, above a line in length; of a glaucous green, nearly ſmooth, and ſlightly rugoſe, above; white and downy underneath; cloſely imbricated. *Flowers* uſually two at the end of each branch, one ſeſſile, the other ſtalked. *Calyx* downy, of numerous, linear-lanceolate, acute, fringed ſcales; the inner ones rather the longeſt, and each tipped with a blueiſh, chaffy, ſpreading point, reſembling a radiant floret. *Seed-down* ſimple, minutely feathery, violet-coloured. *Receptacle* naked, rough, with elevated points. Such is the deſcription of Bergius, who mentions no appendages to the *anthers*, nor does the *receptacle*, or the *ſeed-down*, indicate a *Stæhelina*. Having ſeen neither ſpecimen nor figure, we muſt leave the matter undecided.

12. S. *corymboſa*. Corymboſe Cape Stæhelina. Linn. Suppl. 359. Willd. n. 9. Thunb. Prodr. 143.—Leaves wedge-ſhaped, toothed; downy beneath. Panicles corymboſe. Calyx-ſcales rounded, obtuſe.—Native of the Cape of Good Hope. The *ſtem* is ſhrubby, with hoary, furrowed, leafy *branches*. *Leaves* ſcattered, an inch long, on ſhort ſtalks, abrupt, toothed at the extremity; green and ſmooth above; white, finely downy, ſomewhat ſilky, beneath. *Flowers* numerous, on angular, downy, corymboſe, terminal ſtalks. *Calyx* not half an inch long, of many broad, brown, downy, erect, cloſely imbricated ſcales. *Florets* white or yellowiſh. *Anthers* with a double ſpur at the baſe. *Seed-down* rough, ſimple, ſcarcely faſciculated. *Receptacle* ſmall, cellular, not perceptibly ſcaly. The habit, and the ſpurred *anthers*, ſeem to juſtify us in keeping this ſpecies among the *Stæhelinæ*, notwithſtanding the *receptacle*.

STAFARDA, in *Geography*, a town and abbey of France, in the department of the Stura; 3 miles N. of Saluzzo.

STAFF, BACULUS, an inſtrument ordinarily uſed to reſt on, in walking. Card. Bona obſerves, in his treatiſe of liturgies, that, anciently, thoſe who uſed a ſtaff in the church to lean on, were obliged to lay it by, and to ſtand alone, firm and upright, while the Goſpel was reading, to teſtify their reſpect by their poſture; and to ſhew they were ready to obey Jeſus Chriſt, and to go whereſoever he ſhould command them.

The ſtaff is alſo frequently uſed as a kind of natural weapon, both of offence and defence. The Lacedæmonians never wore any ſwords in the time of peace; but contented themſelves with a thick, crooked ſtaff, which was peculiar to them.

Among the Romans, M. St. Evremond obſerves, blows with a ſtaff were the gentleſt correction they gave their ſlaves; inaſmuch as they received them over their clothes. Among the maſters of honour and arms, it is held a greater affront to be beaten with a ſtaff than with a ſword; becauſe the ſword is the inſtrument of war, the ſtaff the inſtrument of outrage.

Blows with a ſtaff were very ſeverely puniſhed by the French laws: by a regulation of the marſhals of France, in 1653, for reparations and ſatisfactions of honour, it is adjudged, that a perſon, who ſhall ſtrike another with a ſtaff, ſhall be impriſoned a whole year; unleſs ſix months be moderated, upon paying three thouſand livres, applicable to the neareſt hoſpital; beſide which, the offender is to aſk pardon of the offended on his knees, &c. ready to receive from him a like number of blows with a ſtaff; which, on ſome occaſions, the latter may be obliged to give, if he have too much generoſity to do it of himſelf.

By another regulation of the marſhals in 1679, he who ſtrikes with a ſtaff after receiving blows with the fiſt in the heat of a fray, is condemned to two years' impriſonment; and to four, if he ſtruck firſt with the fiſt.

Staff, *A*, is uſed as an inſtrument for taking acceſſible or inacceſſible heights. For the manner of operation, in taking the height of an acceſſible object, ſee Altitude.

Inacceſſible heights may likewiſe be taken by means of two ſtaves. This muſt be done at two ſtations in a right line from the object, at each of which the ſtaves are to be placed in ſuch a manner, that the ſummit, or top of the height, may be ſeen along their tops in the ſame right line. Thus, ſuppoſe A (*Plate* XIII. *Geometry*, *fig.* 17.) the ſummit of the object whoſe height is to be meaſured, D E, F G, the two ſtaves at the firſt ſtation; and R N, K O, the ſame ſtaves at the ſecond, ſo placed, that the points F D A, K N A, are in the ſame right line. Through the point N let there be drawn the right line N P, parallel to F A: wherefore in the triangles K N P, K A F, the angles K N P, K A F, are equal; alſo the angle A K F is common to both; conſequently the remaining angles K P N, K F A, are equal. And P N : F A :: K P : K F. But the triangles P N L, F A S, are ſimilar; therefore P N : F A :: N L : S A. Thence alternately K P : N L :: K F : S A; *i. e.* as the exceſs of the diſtance of the ſtaves at the ſecond ſtation above their diſtance at the firſt, is to the difference of their lengths; ſo is the diſtance of the two ſtations of the ſhorter ſtaves, to the exceſs of the height ſought above the height of the ſhorter ſtaff. Wherefore S A may be found by the rule of three; to which add the height of the ſhorter ſtaff, and the ſum will give the whole inacceſſible height, A B.

Staves may be uſed for meaſuring any diſtance: ſuppoſe A B (*fig.* 18.), to one of whoſe extremities we have acceſs. Let there be a ſtaff fixed at the point A; then going back to ſome ſenſible diſtance, in the ſame right line, let another be fixed in C, ſo that both the points A and B may be covered or hid by the ſtaff C. Likewiſe going off in a perpendicular, from the right line C B, at the point A, let there be placed another ſtaff at H: and in the right line C G K, perpendicular to the ſame C B at the point C, and at ſuch a point of it K, that the points K, H, and B, may be in the ſame right line, let there be fixed a fourth ſtaff. Let there be drawn, or ſuppoſed to be drawn, a right line, H G, parallel to C A. The triangles K H G, H A B, will be equiangular: wherefore K G : G H (= C A) :: A H : A B; *i. e.* as the exceſs of C K above A H is to the diſtance betwixt the firſt and ſecond ſtaff, ſo is the diſtance betwixt the firſt and third ſtaff to the diſtance ſought. Tr. Pract. Geom. p. 22—25.

Staff, *Almucantar's*, *Augural*, *Back*, *Croſs*, *Fore*, *Paſtoral*, *Whip*. See the articles.

Staff, *Jacob's*. See Radius *Aſtronomicus*.

Staff, *Quarter*. See Quarter.

Staff, *Ward*, See Ward-*Staff*.

Staff-*Officers*, in *Military Language*, &c. See Officers.

Staff, *Field*. See Field.

Staff, *Regimental*, conſiſts of the adjutant, quarter-maſter, chaplain, ſurgeon, &c.

Staff, in *Heraldry*. See Baston.

Staff, in *Muſic*, *Riga*, Ital., *Portée*, Fr., the five parallel lines upon which, and between which, muſical characters or notes are written.

Guido Aretin, the great improver of the modern muſic, is ſaid to be the firſt who introduced the ſtaff, marking his notes by ſetting points (.) up and down them, to denote the riſe and fall of the voice; and each line and ſpace he marked at the beginning of the ſtaff, with Gregory's ſeven letters, a, b, c, d, e, f, g.

But others will have the artifice of an older date; and Kircher particularly affirms, that in the Jeſuits' library at Meſſina, he found an old Greek MS. book of hymns, above ſeven hundred years old; in which ſome hymns were written on a ſtaff of eight lines, marked at the beginning with eight Greek letters. The notes or points were on the lines, but no uſe was made of the ſpaces.

The ingenious and learned Dr. Burney has proved that parallel lines were of higher antiquity than the time of Guido. It appears from an ancient MS. treatiſe on muſic by Odo the monk, written about the year 920, that lines began to be uſed in the tenth century. They were eight or nine in number; and at firſt, the ſyllables of the pſalm or hymn that was to be ſung, were placed in the ſpaces between theſe lines: after this an alphabetic character was placed at the beginning of each line, capitals for the grave ſounds, and minuſcules for the acute: to this kind of notation ſucceeded points, a ſcale formed of which Dr. Burney has given from a tract written by the great muſical monk Hubaldus, who flouriſhed about the year 880. He has alſo produced three examples from ancient miſſals, one of which was written about the year 900, cited by P. Martini, in which only one line is uſed to aſcertain the predominant ſound of the chant; a red line for the clef of F, and a yellow one for that of C: and this, he ſays, ſeems to have been the firſt time that a line was drawn through notes of the ſame elevation, and the origin of clefs, which are only Gothic letters corrupted or disfigured.

Vincenzo Gallilei ſays, that a little before the time of Guido, the points were placed on ſeven lines only, without uſing the ſpaces; perhaps in imitation of the ſeven ſtrings of the lyre. The regular ſtaff of four lines was not generally uſed till the thirteenth century. Kircher, indeed, ſpeaks of Guido's uſing five lines and five ſpaces, but, as Dr. Burney ſays, without authority. However, though lines without ſpaces, and ſpaces without lines, had been uſed before the time of Guido, he ſeems to have firſt ſuggeſted the uſe of lines and ſpaces together; and thus the lines, which by ſome had been made as numerous as the notes, were reduced to four: a number which, in miſſals and rituals, of the Romiſh church, has never ſince been exceeded. Indeed the uſe of a line for each note above mentioned, may never have arrived at the knowledge of Guido, who ſpeaks the language of an inventor, with reſpect to lines and ſpaces, more than on any other occaſion: and, if he be allowed the invention of lines and ſpaces, clefs will of courſe accompany them. Burney's Hiſt. of Muſic, vol. ii. p. 34, &c. p. 87, &c.

Staff, in a *Ship*, a light pole erected in different parts of a ſhip, on which to hoiſt and diſplay the colours. The principal of theſe is reared immediately over the ſtern, to diſplay the enſign; another is fixed on the bowſprit, to extend the jack; three more are erected at the three maſt-heads, or formed by their upper ends, to ſhew the flag or pendant of the reſpective ſquadron or diviſion to which the ſhip belongs.

Staff, *Futtock*, or *Puttock-ſtaff Rigging*, are ſhort pieces of rope, ſerved over with ſpun-yarn, to which the ſhrouds are confined at the cat-harpins. Thoſe for the lower and top-maſt rigging are to be made of iron in future in the navy.

STAFF, in *Rope-Making*, is an implement belonging to the nipper, being an oak bar ſeven feet long, and four inches ſquare, one end of which is fixed in an iron ſtrap on the upper plate of the nipper, whilſt on the other end a weight is ſuſpended, ſufficient to preſs the tar out of the yarn. The "nipper" is formed of two ſteel plates, eight inches ſquare, and half an inch thick, with a ſemi-oval hole in each, four inches wide, which, by the upper plate moving, enlarges or contracts, as the tarring of the yarn requires. It is thus fixed: a poſt, twelve inches ſquare, is placed between the kettle and capſtern, with a mortiſe cut eighteen inches long from the kettle's ſurface, and five inches wide. The under plate is turned up on each ſide, to form two grooves, and is let into the front ſide of the poſt from the lower part of the mortiſe: the upper plate has a dove-tail on the back, that ſlides up and down in a groove into the grooves of the lower plate, and by the ſtaff, made faſt to its front, it is elevated or depreſſed, and regulated by a weight ſuſpended at the other end, ſo that the yarn receives no more tar than is required, and what is ſqueezed out drops in a trough, and returns into the kettle.

STAFFS for tops are round, from ſix to eight feet long, and from two and a half to five inches in diameter, which go through a hole in the top, or are confined under it by a bolt and tails: they run on a truck-wheel, as the rope cloſes. See SPINNING-*Wheel.*

STAFF, in *Surgery*. See CATHETER and LITHOTOMY.

STAFF, in *Surveying*, a kind of ſtand, on which to mount a theodolite, circumferentor, plain table, or the like, for uſe. It conſiſts of three legs of wood joined together at one end, whereon the inſtrument is placed; and made peeked at the other, to enter the ground. Its upper end is uſually fitted with a ball and ſocket.

STAFF, *Station*, an inſtrument conſiſting of two rulers that ſlide to ten feet, divided into feet and inches, with a moveable vane or ſight, two of which are uſed with a level; and on the edges there are the links of Gunter's chain divided. Its chief uſe is for the eaſy taking off-ſets. See OFFSET *Staff.*

STAFF, *Shepherd's*, in *Botany*. See TEAZEL.

STAFF-*Tree*. See CELASTRUS.

STAFF, in *Rural Economy*, a meaſure of nine feet, or half a cuſtomary rod. It alſo ſignifies the rod ſet up as a mark in levelling, ſurveying, &c. See LEVELLING.

STAFF *and Band Hedge*, a term applied to that kind of dead fence of this ſort, which is formed and conſtructed by means of ſtakes and bands, or edders and eathers.

STAFF, *Churn*, a term applied to the round upright ſtem, or piece of wood of the ſtaff kind, which, in churning in the old common upright churn, forms the butter from the cream or milk.

A very great and uſeful improvement has lately been made on the ſtaffs of churns of this kind, by Mr. T. Fiſher, an ingenious gunſmith at Ormſkirk, in the county of Lancaſter; which conſiſts in the head or working part of the ſtaff being formed with a ſort of bevil, and its turning upon a ſwivel made of iron.

The two pieces of wood which form the head of the ſtaff have commonly the following dimenſions. Thickneſs one inch and a half, breadth two inches and a half, length thirteen inches, and from that to any other length, according to the ſize of the churn. They are joined together in a croſs-like manner, by halving one into the other in the middle parts. All the edges on the under ſide are rounded, or bevilled off to ſome diſtance, ſo as to elevate or raiſe the middle part a little above the reſt of the head. This croſs-formed head is connected with the ſtaff by means of a ſwivel, which is one inch and three quarters in diameter, being turned perfectly ſmooth and round. There is a ſort of tongue, which is four inches in length from the ſhoulder, and of an oblong form, which is paſſed up the ſtaff, and held in its place by an iron peg; the lower round end of which, to the length of about half an inch, ſerves to ſteady the head of the ſtaff. And there is a button fixed upon the upper ſide of the head, which notches into the ſtaff, and keeps it ſteady in the time of collecting the butter, but when churning, the whole is left perfectly looſe. The lower end of the ſtaff, in this caſe, ſhould be left rather thicker than in the common ſtaff, in order that it may receive the button more perfectly.

STAFF, *Hand*, in *Agriculture*, the name of that part of the common flail which is held in the workman's hand while he is working with it, and to which the ſouple or other part of the flail is attached. The hand-ſtaffs of flails were formerly moſtly connected to the other parts of the tools by means of leather caps and thongs; but the improved method is now by iron caps, made in the manner of round half-circular ſtaples in the middle parts, which connect with and work in the ſame ſort of caps on the ſouples.

STAFF, *Plough Paddle*, a term ſometimes applied to the ſmall ſtaff carried in the body of the plough, which is ſhod with iron, and employed for clearing away the adheſive earthy matter that hangs about the mould-board, and other parts of common ploughs.

STAFF, *Rack*, that ſort of ſtaff which is employed in forming racks for horſes or neat cattle.

STAFF, *Tuck*, the name of that ſort of ſtaff which is made uſe of in emptying dung and ſome other kinds of carts.

STAFFA, in *Geography*, one of the iſlands of the Hebrides, Scotland, is noted in natural hiſtory for its vaſt baſaltic columns and caves. (See BASALT.) This ſmall iſland emerges from the Atlantic ocean, in the midſt of a ſpacious bay, formed by ſeveral iſlands, of which thoſe of Mull, Icolm-Kill, Col, and Tiree, are the chief. In civil government and juriſdiction it is included in the diſtrict of Mull, and ſhire of Argyle, and conſtitutes part of the pariſh of Kill-Ninian. It is about five leagues W. from the iſle of Mull, and three leagues N.N.E. from Icolm-Kill. The form is oblong and irregular, and the whole extends about one mile in length, and half a mile in breadth, with ſteep and craggy coaſts; its ſides are entirely bare, and in many places it exhibits ſuperb baſaltic columns, with various caverns. It is acceſſible only by a ſmall entrance on the weſt ſide, where the ſurface ſlopes towards the ſea; but which will only admit a ſmall boat, and that in calm weather. The moſt elevated part of the iſland is over the cave of Fingall, where it is 214 feet above the ſea, at ordinary tides. The greateſt length of Staffa is about one Engliſh mile, and its breadth half a mile. During the ſummer a few cattle are fed on this iſland, and are attended by a herdſman and his family, who have a ſmall hut. More than half the circumference of the iſland is occupied by grand and regular colonnades of baſaltes, which are completely expoſed to the operations of the ſea: the reſt of the iſland exhibits the ſame baſaltic appearances; but the pillars are bent and twiſted in various directions; ſome lying nearly horizontal, and others forming ſegments of circles. The pillars are chiefly of five or ſix ſides; but ſome of three, four, or ſeven. The diameters vary from one foot to four feet and a half: the ſurface of the large pillars is, in general, uneven; ſome are jointed, having the upper ſurface concave, with a correſpondent convexity in the inferior; but in many the ſurface is plain. The ſpaces between the perpendicular priſms are filled with a yellow ſparry matter, of which the oxyd of iron, ſeparated from the baſaltes, with ſome argillaceous earth, and ſpecimens of zeolitic cryſtals, are the component parts. Near the landing-place the pillars are ſmall, but their magnitude increaſes in the vicinity of the cave of Fingall. This natural curioſity of the iſland is 53 feet wide at the entrance, 117 feet in height, and 250 feet in length. The arch is compoſed of two unequal ſegments of a circle, which form a natural pediment. The maſs by which the roof is crowned, or rather formed, is 20 feet in thickneſs at its loweſt part. It conſiſts of ſmall priſms, inclining in all directions, cloſely cemented with a calcareous matter, and zeolitic cryſtallizations, which afford a ſtriking contraſt with the dark purple hexagons formed by the ends of the pillars, and exhibit the appearance of moſaic work. The bottom of the cave is filled with the ſea. In very calm weather, a boat may ſail into it; but if ſuch an attempt ſhould be made when the waves are in the ſlighteſt degree agitated, the veſſel would be daſhed to pieces. The only way of entering at ſuch times is by a cauſeway on the eaſtern ſide, not more than two feet broad, formed by the baſes of broken pillars, which being conſtantly waſhed by the ſpray, is very ſlippery and unſafe. At the further extremity is another ſmall cave, which, from certain paſſages, emits an agreeable noiſe every time the water ruſhes into it, whence it has acquired the name of the "melodious cave." Beſides the cave of Fingall, there is another, exhibiting the ſame appearances, though on a ſmaller ſcale. It is ſituated on the north ſide of the iſland, and is called the "Corvorant's cave."

Staffa, though one of the greateſt natural curioſities in Europe, or perhaps in the world, has been till lately little noticed, and indeed ſcarcely known. The firſt perſon who particularly called the attention of the learned to this ſingular iſle was Mr. Leach, a native of Ireland; who, in the year 1772, having been on a viſit to Morven, in Argyleſhire, in a fiſhing excurſion, was charmed with the peculiar appearance of its rocks, and landed upon it. Soon afterwards, ſir Joſeph Banks, Dr. Von Troil, the learned biſhop of Linckoeping, and others, in their voyage from Iceland, anchored in the Sound of Mull; and having been informed by Mr. Leach of the wonders which Staffa afforded, they viſited the iſland, and an account of it was communicated by ſir Joſeph to Mr. Pennant, who publiſhed it in his "Tour to the Hebrides." Since that time it has excited the attention of various naturaliſts, who have given accounts of it in their reſpective works: among whom, M. de St. Fond and Dr. Garnett may be principally mentioned. The former, who viſited the Britiſh dominions on a voyage of reſearch, thus expreſſes himſelf reſpecting Fingall's cave. "This ſuperb monument of a grand ſubterraneous combuſtion, the date of which has been loſt in the lapſe of ages, preſents an appearance of order and regularity ſo wonderful, that it is difficult for the coldeſt obſerver not to be ſingularly aſtoniſhed by this prodigy, which may be conſidered as a ſort of natural palace. I have ſeen many ancient volcanoes, and I have given deſcriptions of ſeveral baſaltic cauſeways and delightful caverns in the midſt of lavas, but I have never found any thing which comes near to this, or can bear any compariſon with it, for the admirable regularity of its columns, the height of the arch, the ſituation, the form, the elegance of this production of nature, or its reſemblance to the maſter-pieces of art, though art has had no ſhare in its conſtruction." Similar to this are the animated obſervations of the learned prelate before-mentioned. "How ſplendid," ſays he, "do the porticoes of the ancients appear in our eyes, from the oſtentatious magnificence of the deſcriptions we have received of them: and with what admiration are we ſeized on ſeeing the colonnades of our modern edifices! But when we behold the cave of Fingall, formed by nature in the iſle of Staffa, it is no longer poſſible to make a compariſon, and we are forced to acknowledge that this piece of nature's architecture far ſurpaſſes that of the Louvre, that of St. Peter at Rome, all that remains of Palmyra and Pœſtum, and all that the genius, taſte, and luxury of the Greeks, were ever capable of inventing." In Pennant's Tour in Scotland, 4to. 1790, and St. Fond's Travels, are accounts of this iſland, with plates.

STAFFELSTEIN, a town of Bavaria, in the biſhopric of Bamberg, on the Lauter; 16 miles N.N.E. of Bamberg. N. lat. 50° 8′. E. long. 11° 3′.

STAFFORA, a river of Italy, which paſſes by Voghera, and runs into the Po, 8 miles W.S.W. of Pavia.

STAFFORD, a borough, market, and county-town, in the ſouth diviſion of the hundred of Pirehill, Staffordſhire, England, is ſituated on the north bank of the river Sow, at the diſtance of three miles from its junction with the Trent: and is 16 miles N.W. from Lichfield, and 140 miles in the ſame direction from London. The earlieſt authentic mention of the town is in the Saxon chronicle, A.D. 913, when Ethelfleda, counteſs of Mercia, ſiſter of king Edward the Elder, built a caſtle here, of which no veſtige now remains: and Camden ſtates, that in the following year king Edward built a tower on the north bank of the river. This tower Mr. Pennant ſuppoſes to have ſtood on the mount called Caſtle-hill, and now diſtinguiſhed by the appellation of Bully-hill. Near it is an ancient ſtructure, called Caſtle-church, built in various ſtyles of architecture. Nothing worthy notice is mentioned reſpecting this town, from the erection of theſe caſtles till the Norman conqueſt, when it appears from the Domeſday ſurvey, that the king had here "eighteen burgeſſes in demeſne, and twenty manſions of the honour of the earls." The ſame record ſtates that the king built a caſtle here, the cuſtody of which was given to Robert de Tonei, who in conſequence took the name of Stafford. This caſtle does not appear to have ſtood long; but by whom, or on what account deſtroyed, is unknown. It was, however, reſtored in the reign of Edward III., and continued till the ſeventeenth century; when being garriſoned in ſupport of the royal cauſe, it was taken by the parliament's forces, and demoliſhed. Stafford appears to have been a town of conſiderable importance prior to the Norman conqueſt: early in the tenth century it was conſidered the chief town of the diſtrict: in the Domeſday-book it is termed a city, and was at that time governed by two bailiffs: but the earlieſt charter of incorporation now extant was granted by king John, in the ſeventh year of his reign. This deed, however, evinces that it was incorporated at a much earlier period; as it merely confirms privileges enjoyed from "remote antiquity," and does not confer any new. The word uſed in this charter to point out the previous exiſtence of theſe privileges is *antiquitus*, which certainly would not have been uſed to denote a period then ſo recent as that of the Conqueſt. King John's charter was confirmed by Edward VI., and many new privileges added to the town. Queen Elizabeth eſtabliſhed the aſſizes and ſeſſions here by act of parliament, in the firſt year of her reign. Mr. Gough ſtates, that in her progreſs in 1575, ſhe perceived the town to be on the decline; and being informed that it was partly owing to the removal of the aſſizes, ſhe ſaid ſhe would reſtore that privilege for ever.

The form of Stafford is that of an irregular ellipſis, the greateſt diameter whereof extends from ſouth-eaſt to north-weſt. The ſituation, though low, is very pleaſant: the ſtreets are well paved, and the houſes in general built of ſtone, in a compact and regular manner. It anciently had four gates, and was defended, except on the ſide next the Sow, by a wall, and a ditch ſupplied with water from the river. When taken by the republican army in 1643, the wall was razed, and the ditch filled up, ſo that no remains of either can now be diſcovered. Under the charter of Edward VI. the civil government of Stafford was veſted in a mayor, a recorder, ten aldermen, twenty common-councilmen, a town-clerk, and two ſergeants at mace. Two repreſentatives are ſent to parliament, and have been ſo ever ſince the 23d year of Edward I. The right of election is in the mayor and burgeſſes; the number of voters being about four hundred. The chief manufactures in the town are thoſe of boots, ſhoes, and cutlery. Tanning is likewiſe carried on to a conſiderable extent, as well for the exportation as home conſumption of leather. A weekly market is held on Saturdays, and ſeven fairs, annually. In the year 1811, the population of Stafford was returned to parliament at 4868; the number of houſes 885. The immemorial cuſtom of *Borough Engliſh* is ſtill retained in this town, whereby the youngeſt ſon ſucceeds to property, as heir at law, in preference to the elder children. Though Stafford may with propriety be conſidered as only one pariſh, there are two churches, St. Mary's and St. Chad's. The former is a ſpacious cruciform ſtructure, conſiſting of a nave, two ſide aiſles, a tranſept, and a chancel of three aiſles, with an octagonal tower in the centre. This church appears to be of very remote origin: it has, however, been almoſt entirely rebuilt, but ſome remains of the ancient ſtructure are ſtill viſible. The general ſtyle of architecture is the early pointed. The font is a ſingular remnant of antiquity, very large, and aukwardly conſtructed. Its height is three feet three inches: the lower part is two feet ſquare; and is ornamented on three ſides with human figures lying flat on their faces: on the fourth ſide is the figure of a ram. Among a variety of monuments, ancient and modern, in this church, thoſe moſt worthy of notice are, an altar-tomb, in honour of lord Edward Aſton, of Tixal, and his wife lady Ann; a monument to the memory of ſir Edward Aſton, who erected the ancient manſion of Tixal, tem. Hen. VIII. and his lady Joan; and one to lady Barbara Crompton, who, as the inſcription informs us, "lyeth interred in the pariſh-church of St. Gregory, by St. Paules, London." Near the church, to the weſtward, formerly ſtood an ancient building, which Mr. Pennant conjectures to have been the dean's houſe. The church of St. Mary, anterior to the reformation, was collegiate: king Stephen, at the commencement of his reign, beſtowed it on the biſhop and chapter of Lichfield and Coventry. At the diſſolution, a dean and thirteen prebendaries were attached to it. The other church of Stafford, St. Chad, is a very ancient edifice. Early in the laſt century it was caſed with brick; but ſome portions of the buttreſſes of the original building are ſtill viſible. St. Chad's pariſh is of very ſmall extent, not containing more than 20 houſes, the rents of which are chiefly paid to the dean and chapter of Lichfield cathedral. Beſides the churches, there are places of worſhip for the Quakers, Independents, Preſbyterians, and Methodiſts, of which ſects the two latter are numerous. Of the other public buildings, the moſt conſpicuous are; the county hall, a ſpacious modern edifice, ſituated near the centre of the town: it extends a hundred feet in front, and contains many handſome apartments. Behind the hall is a convenient market-place. The county infirmary, a plain building, in the Foregate; erected about the year 1772, according to Mr. Pennant; and ſupported by voluntary contributions, to the annual amount of nearly 900*l.* The county gaol, ſituated oppoſite to the infirmary; an extenſive modern ſtructure, containing about 150 cells or apartments. The free-ſchool, an ancient building, founded and endowed (as appears by an inſcription in St. Mary's church) by king Edward VI., in the year 1550. Leland ſays, "there is a fre ſchool for grammar in Stafford, made by ſir Thomas Countre, parſon of Ingeſtre, by Heywodde and Syr Randol, a chantre prieſt of Stafford." Various alms-houſes, at different periods, have been built and appropriated for the comfortable accommodation of the aged poor: each tenement has a garden annexed to it. Previous to the diſſolution of religious houſes, Stafford contained ſeveral monaſtic eſtabliſhments. At the north end of the walls ſtood a houſe of Franciſcans, or grey friars, founded, Erdeſwick ſays, by ſir James Stafford, of Sandon. King Henry VIII. granted it to James Leveſon. A priory of black canons was founded here about the year 1180, and dedicated to St. Thomas á Becket, ten years after his death. Richard Peche, biſhop of Lichfield and Coventry, had ſuch a partiality for this houſe (of which he is by ſome authors conſidered the founder), that, reſigning his ſee, he entered himſelf as one of the members, and ſo continued the remainder of his life. At the diſſolution it was granted to Rowland, biſhop of Lichfield. This houſe, which was ſituated on the banks of the river Sow, about two miles to the E. of Stafford, was incloſed by a ſtrong ſtone wall; ſome remains of the building are ſtill extant. About the middle of the fourteenth century, the Auſtin friars founded a religious eſtabliſhment at the ſouthern extremity of the town; a portion of ground having been granted to them by Ralph, lord Stafford, for that purpoſe. This houſe was given by queen Mary to Thomas Neve and Giles Iſam.

About a mile and a half ſouth-weſt from the town, on the ſummit of a hill, are the remains of the caſtle of the barons of Stafford: the chief portion now ſtanding is the keep, of which each angle is ſurmounted by a ſmall octangular tower. At a ſmall diſtance to the ſouth of the caſtle ſtood the manor-houſe, the uſual reſidence of the ancient and powerful family to which this town has given the title of baron, viſcount, and earl, from the time of William the Conqueror till the beginning of the laſt century, when it became extinct; but was again revived in the year 1786, by the elevation of earl Gower to the dignity of marquis of Stafford, which title is now enjoyed by his ſon, the ſecond marquis. Among the more diſtinguiſhed natives of this town we find John Stafford, a Franciſcan friar, a philoſopher and divine of conſiderable celebrity, born towards the cloſe of the fourteenth century; Thomas Aſheburn, an eminent divine of the ſame century, who diſtinguiſhed himſelf as a ſtrenuous opponent of Wickliffe and his new doctrines; Edmund Stafford, biſhop of Exeter, and chancellor in the reigns of Richard II. and Henry IV.; Thomas Fitzherbert, a learned and able writer of the ſixteenth and ſeventeenth centuries, who was born in 1552, and died in 1640, in the 88th year of his age.

About three miles weſt from Stafford, on a lofty mount, is an intrenchment, called Billington Bury. Its area is circular, including ſeveral acres, and is ſurrounded in ſome parts by one, and in others by two deep ditches. Mr. Pennant conſiders this fortification as having been originally a Britiſh poſt, ſubſequently occupied by the Saxons, whoſe ſtations have generally the addition of borough or bury.

At the diſtance of four miles ſouth from Stafford, in the angle formed by the junction of the rivers Sow and Trent, is Tixal Hall, the ſeat of Thomas Clifford, eſq. The preſent edifice is a plain modern brick building; but in front of it is an old gateway, ornamented with three ſeries of columns, built by ſir Walter Aſton. Behind this gateway ſtood the ancient manſion, of which ſome remains are ſtill viſible, erected by ſir Edward Aſton, in the beginning of Henry VIII.'s reign. Adjoining to the park which ſurrounds the manſion is Tixal Heath, diſtinguiſhed by two remarkable tumuli, one called the King's, the other the Queen's Low. But why ſo named, or on what occaſion conſtructed, no account is extant. Two urns, ſuppoſed to be of Roman workmanſhip, were found near them early in the laſt century.

Adjoining Tixal is Ingeſtre Hall, an old manſion, built in the reign of queen Elizabeth, the ſeat of earl Talbot. Near the houſe is the village-church, which was built in 1673, by Walter Chetwynd, eſq. the then poſſeſſor of this eſtate.

On Hopton Heath, adjoining Ingeſtre, a ſevere action was fought between the parliamentary and king's forces, in the time of the civil wars of Charles I.—Hiſtory and Antiquities of Staffordſhire, &c. by the Rev. Stebbing Shaw, folio, 1798. Beauties of England and Wales, Staffordſhire, by J. Nightingale, 8vo.

Stafford, a county of Virginia, bounded N. by Prince William county and E. by the Patowmac; containing 9830 inhabitants, of whom 4195 are ſlaves.—Alſo, a townſhip of Connecticut, in Tolland county, on the S. line of Maſſachuſetts, 12 or 15 miles N.E. of Tolland. In this townſhip is a furnace for caſting hollow ware, and a medicinal ſpring, which is the reſort of valetudinarians. It contains 2235 inhabitants.

Stafford, *New*, a townſhip of New Jerſey, in Monmouth county, adjoining Dover on the S.W. and containing 1239 inhabitants.

STAFFORDSHIRE is an inland county, ſituated nearly in the centre of England, between 52 and 54 degrees N. latitude, and between one and three degrees W. longitude from London. It is in ſhape an irregular parallelogram; and is bounded on the N. by Cheſhire and Derbyſhire, on the E. by Leiceſterſhire, on the S. by the counties of Warwick and Worceſter, and on the W. by Shropſhire. Its greateſt length from N.N.E. to S.S.W. is about 60 miles, and its greateſt breadth from E. to W. 38 miles. The ſuperficial contents are about 780,800 acres, of which 100,000 are paſture, 500,000 arable, and the remaining 180,800, woods, waters, waſtes, &c.

Ancient State: Hiſtorical Events.—This county appertained to the Cornavii of the Britons, to the diviſion of Flavia Cæſarienſis of the Romans, and was a part of the kingdom of Mercia during the Saxon heptarchy. Bede calls the inhabitants Angli-Mediterranei, the midland Engliſh. The two Roman military ways, Watling-ſtreet and Icknield-ſtreet, paſs through this county. The former enters it out of Warwickſhire, near Tamworth, and running weſtward paſſes into Shropſhire. Icknield-ſtreet alſo enters from Warwickſhire at the village of Hanſworth, near Birmingham, croſſes Watling-ſtreet, and enters Derbyſhire at Monk's bridge. The Roman ſtations in this county that are known, are Pennocrucium, near Stretton; and Etocetum, at Wall near Lichfield. But Salmon gives to Staffordſhire four Roman ſtations, which, he ſays, are Mediolanum, at Knightley; Uriconium, at Wrotteſley; Uxacona, at Wall-Lichfield; and Etocetum, at Barbeacon. The firſt of theſe ſtations Camden poſitively fixes in Montgomeryſhire; and biſhop Horſley places it on a ſlip of land incloſed by the Tern and another river. Salmon aſſigns Pennocrucium to Oldbury, in Warwickſhire, and refers to Antoninus's ſecond Iter for his authority; but Plot, Gale, Horſley, and Stukeley, coincide in opinion that Penkridge is the ſcite of that ſtation. The ancient inhabitants of Staffordſhire, in the opinion of Dr. Plot, were the Iceni; but in this he ſtands unſupported: Shaw ſays that tribe was undoubtedly of Derbyſhire. Camden and Gough will not allow that they extended beyond Huntingdonſhire, weſtward; while Salmon confines them to Norfolk and Suffolk. Shaw ſuppoſes that the Ordovices were the original inhabitants of this diſtrict, and it is generally agreed that they poſſeſſed it many centuries before the Chriſtian era. Theſe were an intrepid warlike people, whoſe territories compriſed a great portion of Wales and ſeveral counties of England. But they were diſturbed in their poſſeſſions by the Cornabii, who, breaking through the limits of their original ſettlements on the banks of the Dee, conquered a large tract of country to the weſt and north-weſt, and eſtabliſhed a monarchy, of which Condate was the capital. The Brigantes, in their turn ſubdued a portion of the territories of this tribe a ſhort time previous to the arrival of the Romans. On this event the metropolis was transferred from Condate to Uriconium, now Wroxeter, where it continued a conſiderable time, till the Romans extended their conqueſt into the interior of the country. During the ſanguinary conteſts which enſued, little is recorded reſpecting this diſtrict and its inhabitants, but that they heroically reſiſted the invaders, and though at length compelled to ſubmit, their courage and ardour for freedom excited the admiration of their conquerors. The Cornabii, after the ſubjection of their country, appear to have been the friends and allies of the Romans. It is remarkable that after the decline of the Roman power, the appellation Cornabii never occurs in the annals of Engliſh hiſtory. When the Britons experienced a ſecond ſubjugation by the Saxons, and the heptarchy was eſtabliſhed, Staffordſhire formed a part of the kingdom of Mercia, which extended over all the midland counties, and was founded by Crida in the year 585. During the repeated invaſions of the Danes, this county ſuſtained a conſiderable part of the calamities conſequent on their cruelty and rapacity. Several ſanguinary battles took place within the kingdom of Mercia; in Staffordſhire particularly, two victories were obtained over the Danes in the reign of Edward the Elder. On the partition of England between Edmund Ironſide and Canute, this county, as part of Mercia, was awarded to the latter. After the Norman conqueſt, William divided the eſtates of the Mercian earls among four of his principal followers, Hugh de Montgomery, earl of Arundel; Robert de Stafford, Henry de Ferrars, and William Fitz-Anſculph; the laſt of whom held twenty-five manors in this county. The other principal landholders beſides the king, were the biſhop of Cheſter, the abbots of Weſtminſter and Burton, the church of Rheims, and the canons of Stafford and Wolverhampton. During the contention between the royal houſes of York and Lancaſter, a deciſive battle was fought at Bloreheath, in this county, between the Yorkiſts under the earl of Saliſbury, and the Lancaſtrians under lord Audley, when the latter, with double the force and ſuperior poſition, was completely defeated, himſelf ſlain, and 2400 Cheſhire gentlemen, whoſe attachment to king Henry led them into the van, alſo fell in the action.

In the civil war of the ſeventeenth century, Staffordſhire was conſiderably engaged: Stafford ſurrendered to the parliament's forces, and Lichfield was ſeveral times taken and retaken by the contending parties. In this county Charles II. lay concealed after the fatal battle of Worceſter, till he had an opportunity of eſcaping. The circumſtances attending his concealment, the difficulties he ſuſtained, and the unſhaken loyalty of his friends, are amply detailed by Mr. Shaw in his General Hiſtory of Staffordſhire.

Eccleſiaſtical Hiſtory.—Staffordſhire did not receive the light of the goſpel till the reign of Penda, king of Mercia, whoſe ſon, Peadda, was converted to Chriſtianity by the venerable Bede. This was ſoon declared the eſtabliſhed religion of Mercia, and the cathedral of Lichfield was founded, where the epiſcopal ſee of Mercia was fixed in 669; but it was ſoon afterwards divided into five ſeveral dioceſes, and Lichfield, Worceſter, Hereford, Leiceſter, and Sidnaceſter, choſen for the reſpective ſees. In the year 786, at the requeſt of king Offa, pope Adrian advanced Lichfield to the dignity of an archbiſhopric; but this diſtinction was continued only till the death of Offa, when pope Leo reduced it to its former rank. About the year 1067 the epiſcopal ſeat was removed to Cheſter, and thence ſoon afterwards to Coventry, where it continued till the end of the thirteenth century, when Walter de Langton was appointed biſhop of Lichfield and Coventry. From this period nothing remarkable occurred in Staffordſhire, connected with church hiſtory, previous to the reformation, when Lichfield cathedral was deſpoiled of the rich ſhrine of St. Chad, and the ſee of Coventry ſeparated from it. The two biſhoprics remained diſtinct till the reſtoration, when they were again united in the perſon of Dr. John Hacket. Since that time the dioceſe has undergone no particular alteration. Staffordſhire, which is compriſed in this ſee, contains 181 pariſhes.

Civil Diviſion.—Staffordſhire is divided into five hundreds; Totmanſlow, Pyrehill, Cuddleſtone, Offlow, and Seiſdon: and contains one city, Lichfield, and twenty-three other market-towns, *viz.* Stafford, Wolverhampton, Walſall, Burton-on-Trent, Uttoxeter, Newcaſtle, Leek, Stone, Cheadle, Eccleſhall, Rudgeley, Tamworth, Tutbury, Abbot's-Bromley, Breewood, Penkridge, Cannock, Wedneſbury, Burſlem, Handley-Green, Lane-End, and Longnor. Ten members are returned to the imperial parliament from this county, *viz.* two for the ſhire, and two each for Lichfield, Stafford, Newcaſtle, and Tamworth. According to the population ſurvey of the year 1811, this county contained 57,040 houſes, occupied by 295,153 perſons; of whom 34,011 families were chiefly employed in trade and manufactures, and 18,361 in agriculture.

General Aſpect, Soil, and Climate.—The appearance of the county varies in different diſtricts. The middle and ſouth portions are generally level: among the few exceptions are the hills of Dudley and Sedgeley, the quartoſe and ragſtone hills of Rowley, and thoſe of Clent and Barbeacon. The grounds of Byſhbury and Eſſington, and ſome ſituations near Tettenhall and Enville, as well as on Cannock-heath, are alſo conſiderably elevated. The latter portion of the county was in ancient times covered with oak, but moſt of theſe have been deſtroyed: indeed ſcarcely a tree now remains to enliven the proſpect, through an extent of 2500 acres. The northern portion of the county is of an oppoſite character to that on the ſouth. Here the ſurface is moſtly bleak and hilly: only a few of the eminences, however, riſe to any remarkable elevation. The ſummit of Bunſter, near Ilam, was found by Mr. Pitt, in the courſe of his "Agricultural Survey," to be 1200 feet above the level of the Thames. The Weever hills, and ſome other points, he reports as aſcending even 1500 feet. The general elevation of this diſtrict above the ſouthern is eſtimated at from one to two hundred yards. That portion of it called the moorlands, is the commencement of that range of mountains which extend through the centre of England, till they enter Scotland, acquiring different appellations in their progreſs, and increaſing in altitude as they approach the north. The *ſoil* is extremely varied. The arable ſoils may be divided generally into the argillaceous, or ſtiff and ſtrong clayey; the arenaceous, or looſe, light, and ſandy; the calcareous, or lime earth; and a mixed or compound ſoil, or loam compoſed of the foregoing, with the addition of ſtones and other matters. The *climate* of this county inclines to wet: the annual rains are calculated at upwards of 36 inches, and thus exceed by nearly 16 inches the average computation of rain in London. A great quantity of ſnow falls in the moorlands, which doubtleſs is a principal cauſe of the piercing cold which prevails in that diſtrict.

Rivers.—Staffordſhire abounds with rivers, but none of them are navigable, at leaſt within the county. The principal are the Trent, the Dove, the Tame, and the Blythe. The Trent, which may be conſidered as the third river of England, waters, in its courſe to the ſea, ſome of the moſt fertile and beſt cultivated diſtricts of the kingdom. During its paſſage through Staffordſhire, its banks are covered with luxuriant meadows. In the vicinity of Trentham, the ſeat of the noble family of Gower, the efforts of art have greatly added to the natural beauty of the river, by ſwelling it into an expanſive lake. Paſſing the town of Stone, it flows through a valley diverſified with a variety of elegant parks; of which that of Wolſey, bordering on the chaſe of Cannock, is one of the moſt remarkable for the romantic beauty of its ſcenery. Purſuing its courſe, the Trent becomes the boundary between the counties of Stafford and Derby, till its junction with the river Dove; then, croſſing Derbyſhire, it runs through the counties of Nottingham and Lincoln, and at length pours its waters into the Humber. The Dove takes its riſe among the hills in the moorlands, near the points where the counties of Stafford, Derby, and Cheſter meet. From the declivity of its channel, its waters flow with uncommon rapidity: in ſome places it daſhes precipitately over rugged rocks; in others it is diſtinguiſhed by gentle caſcades. It falls into the Trent near Burton, on the confines of Derbyſhire. The Tame, another river of conſiderable ſize, ſprings from ſeveral ſources in the vicinity of Walſall and Coleſhill, enters Warwickſhire near Birmingham, returns into Staffordſhire at Tamworth, and finally joins the Trent. The Blythe riſes in the neighbourhood of Watley moor, in the northern diſtrict. Its courſe is nearly parallel to the Trent, into which it falls near King's-Bromley.

Canals.—Although an inland ſituation, without navigable rivers, appears to labour under peculiar diſadvantage for the purpoſes of trade; yet in Staffordſhire the deficiency is amply compenſated by the number and extent of the canals, with which this county is ſo largely ſupplied. The principal are the Grand Trunk Canal, the Coventry and Oxford, and the Birmingham Canal. Theſe, with their numerous branches and ramifications, have already been particularly deſcribed. See CANAL.

Lakes and Springs.—This county affords but few lakes, and thoſe of no great conſequence. Thoſe moſt worthy notice are that of Aquilate, which extends 1848 yards in length, and 672 in breadth; and Ladford Pool, which occupies the ſpace of about 60 acres. Salt ſprings are found in various places. The moſt conſiderable are thoſe in the pariſh of Weſton, whence ſalt is produced, equal in quality and colour to that of any part of the kingdom.

Minerals.—The number and value of the mineral productions of Staffordſhire claim particular notice. Coal is abundant: upwards of 50,000 acres have been aſcertained to contain an inexhauſtible ſupply, near enough to the ſurface to be eaſily raiſed. From the earlieſt times to the preſent, the conſumption does not appear to have exceeded a tenth part of the whole. In the ſouthern diviſion of the county, the coal diſtrict extends in length from the interior of Cannock-heath to the vicinity of Stourbridge, and in breadth from Wolverhampton to Walſall. To the north, likewiſe, it abounds in the neighbourhood of Newcaſtle and the Potteries, Lane-End, Hollybruſh, Cheadle, and Dillhorne. At Handley-Green a very peculiar ſpecies is dug, called the Peacock coal, from the priſmatic colours it diſplays. Limeſtone is ſtill more abundant than coal. At Sedgeley and Dudley-caſtle hills, Ruſhall and Haywood, and on the north-eaſt moorlands, the quantity is immenſe. The lime-works upon Caldon Low, and near the Weever hills, are particularly extenſive. This ſtone is, in ſome places, of a marble quality, and capable of taking a fine poliſh. In other parts it is chiefly compoſed of trelmintholopi, or petrified marine ſubſtances of the animal kind. Iron ore is plentiful throughout the coal diſtrict. Near Wedneſbury, Tipton, Bilſton, and Sedgeley, and to the weſt of Newcaſtle, it is peculiarly excellent and abundant. The ſtrata are generally ranged beneath a ſtratum of coal. Iron-works of great extent have been recently eſtabliſhed on the banks of the Birmingham Canal; and the trade is ſo rapidly increaſing, as to afford a proſpect of its precluding the neceſſity of any conſiderable importation. Copper and lead ore alſo abound in this county. A copper-mine is worked at Mixon, near Leek; but a more important one at Ecton-hill, near Warſlow, on the eſtate of the duke of Devonſhire. This hill has likewiſe a conſiderable vein of lead; and another of the ſame mineral has been found near Stanton-moor. In this part of the county, but particularly at Whiſton, Oakmoor, and Cheadle, ſmelting and braſs-works are carried on to a conſiderable extent. Quarries of good free-ſtone for various purpoſes are found in the different diſtricts. A durable kind for building, eaſily raiſed in blocks of any dimenſion, is found at Tixal. Alabaſter was formerly dug in great quantities, particularly on the banks of the Dove; but though it ſtill exiſts in plenty, very few of the quarries are now wrought. This county alſo yields various kinds of marble: that ſpecies, to which the name of rance-marble is given, abounds on Yelperſley Tor, and the adjacent hills. Clays of every denomination are abundant. Amblecot produces a clay of a dark-blue colour, of which are made the beſt glaſs-houſe pots of any in England. Glaſs-houſes have, in conſequence, been erected in the neighbourhood; and great quantities of the clay are ſent to different parts of the kingdom. Potters' clay of various ſorts is found here, particularly in the vicinity of Newcaſtle, where the potteries are chiefly carried on. Yellow and red ochre, and other earths uſed for colouring and painting, are among the productions of this county. At Darlaſton, near Wedneſbury, is a blue clay, which is ſold to glovers to dye aſh-colour. A black chalk is found in the beds of grey marble in Langley Cloſe; and under a rock near Hemley Hall is a reddiſh earth, nearly equal to the red chalk of France.

The farms of Staffordſhire are of all extents, from fifty acres to five hundred; but the number of the ſmaller has been lately much diminiſhed. The rent of land varies from 15*s.* to 40*s.* *per* acre, making the average about 25*s.* The cultivated lands of this county are nearly all incloſed, not more than 1000 acres ſtill remaining open. The fences in the ſouthern part are chiefly raiſed from quickſets, among which the white thorn is moſt approved.

Timber, Plantations, and Woodlands.—This county, notwithſtanding the great recent conſumption, is abundantly ſtocked with wood of every deſcription. Lord Bagot's eſtate, near Abbot's-Bromley, contains ſeveral acres of oaks, not to be ſurpaſſed in quality by any in the kingdom: the timber in many of them is to the height of ſixty or ſeventy feet. Chillingworth eſtate ranks next to this for the value of its woods. Thoſe at Beaudeſert, the ſeat of the earl of Uxbridge, and thoſe at Llimley, the property of lord Dudley, are alſo very extenſive. Teddeſley has very conſiderable plantations. Manſley wood is a coppice of fine oak. Wotteſley, Fiſherwick, Trentham park, Sandwell park, Enville, and Hilton, diſplay abundance of well-grown trees of every deſcription.

Waſte Lands.—The extent of uncultivated lands in this county is very great; being computed by Mr. Pitt to amount to an hundred thouſand acres. The chief waſte diſtricts in the ſouthern parts are Cannock-heath and Sutton-Coldfield, with Swindon, Wombourn, and Fradley commons. In the north are Morredge, Wetley-moor, Stanton-moor, Hollington-heath, Careſwell-common, and Needwood foreſt; which laſt, however, has been in part recently incloſed and cultivated.

Manufactures and Commerce.—Various branches of manufacture are carried on to a great extent, particularly in the ſouthern parts of the county: the chief are hardware articles, nails, glaſs, toys, japanned goods, and potters' ware; with productions in cotton, ſilk, leather, woollen, and linen. The manufacture of glaſs is moſt conſiderable in the vicinity of Stourbridge, where many ſpacious glaſs-houſes have been built. The potteries occupy an extent of ten miles, toward the north part of the county: theſe have acquired great reputation from the ingenious Mr. Wedgewood. (See Potteries.) Wolverhampton and the neighbouring villages are diſtinguiſhed for the manufacture of locks: buckles, ſteel-toys, and watch-chains, are among the eſteemed productions of that town. The ſtaple manufacture of Walſall and its vicinity is chiefly ſhoe-buckles, claſps, and ſadlers' ironmongery. Nail-making, in many country pariſhes, is a ſource of employment to great numbers of men, women, and children. Bilſton furniſhes a variety of plated, lackered, japanned, and enamelled goods. At Wedneſbury the gun-trade is extenſive. At Darlaſton, Willenhall, and the adjacent villages, tobacco and ſnuff-boxes are wrought in various modes. Stafford and its neighbourhood exhibit numerous articles in the cutlery and leather-trade: the hat manufacture is alſo carried on there, and in ſome other towns, on an extenſive ſcale. Tin and braſs are among the common productions of the county. The cotton manufactures at Roceſter, Fazeley, Tamworth, Burton, and Tutbury, are very conſiderable; as is likewiſe the ſilk-trade of Leek, and that of tape at Cheadle and Teyn. The woollen manufacture is but comparatively trifling; moſt of the raw wool being ſold into the clothing and ſtocking diſtricts. The making of linen is moſtly confined to private families, for their own uſe.

It is worthy of obſervation, that the original wooden almanac of the Norwegians and Danes is ſtill in uſe in this county, under the appellation of the Staffordſhire clogg. Engravings of this calendar, ſomething different from each other, may be ſeen in Dr. Plot's Natural Hiſtory of the County, and in Camden's Britannia, by Gough. The principal antiquities in this county are the cathedral at Lichfield; Tutbury caſtle and church; Dudley caſtle and priory; Eccleſhall caſtle; Croxton abbey; Alton caſtle; Wolverhampton church; bridge and abbey, at Burton-upon-Trent; Darleſton caſtle; Tixal manor-houſe; Hilton abbey; Rowton priory; Uttoxeter church; Careſwell caſtle; Chartley caſtle; Heyley caſtle.

Authorities.—Hiſtory, &c. of Staffordſhire, by the Rev. S. Shaw, 2 vols. folio, 1798, &c. an unfiniſhed work. General View of the Agriculture of the County of Stafford, by William Pitt, 8vo. 1808. The Natural Hiſtory of Staffordſhire, by Dr. Plot, fol. 1686. A Map of the County, begun in 1769, and finiſhed in 1775, by William Gates, ſix ſheets. Account of Staffordſhire, in the Beauties of England, vol. xiii.

STAFFURTH, a town of Germany, in the principality of Anhalt-Bernburg; 9 miles N.W. of Bernburg.

STAFLEFIT, a town of Pruſſia; 7 miles S. of Culm.

STAG, or *Red Deer*, or *Hart*, in *Zoology*. See CERVUS *Elaphas*. See alſo DEER, HART, HUNTING, and SHOT.

STAG, in *Rural Economy*, a term applied provincially to a young horſe.

STAG-*Beetle*, in *Natural Hiſtory*, is the LUCANUS *Cervus* of Linnæus; which ſee.

STAG-*Evil*, or *Hart*, in horſes and neat cattle, a kind of univerſal cramp or convulſion. See HART.

This is a diſeaſe with which young horſes are not unfrequently affected. It moſtly comes on after much expoſure to ſevere cold, or a high degree of cold moiſture, where heat takes place ſuddenly afterwards, and ſometimes in cooling too quickly after great heat. It attacks the whole body, but more particularly the joints, with a ſort of ſoreneſs, rigidity, and ſtiffneſs, which cauſe the animals to move about in a ſlow, aukward, almoſt lifeleſs manner. They gradually fall off in their appetites, and become incapable of performing any kind of labour, and often even the mildeſt exerciſe diſtreſſes and inconveniences them in a high degree.

In its removal, calomel, with opium and the powder of gum guaiacum, may be firſt had recourſe to in the form of a ball, made up with balſam copaiva, for ſome days; when the uſe of warm cordial ſtrengthening drinks or drenches, with oak or Peruvian bark in fine powder, may be found neceſſary to complete the cure; the horſe during the time being made to take as much gentle exerciſe as poſſible. And the uſe of a good dry graſs paſture is not unfrequently of great benefit in completing the removal of the diſorder.

Neat cattle are likewiſe frequently ſubject to a diſeaſe of the ſame nature, which, after much expoſure to intenſe cold, comes on with a ſtiffneſs in the joints, which is attended with a lumpy ſwelling on them and the legs, after a little time, without any inflammatory appearances. This ſtiffneſs and ſoreneſs ſometimes extend over the whole body, ſo that the beaſts become incapable of riſing, when down, without aſſiſtance. Where the chine or back is particularly affected, the diſeaſe is moſtly denominated the *chine fellon*; but where the joints have more of the diſorder than any other part, it is commonly termed the *joint fellon*, or *joint evil*; and where the whole body is deranged and diſordered, it has often the name of *cold fellon* given it.

The diſeaſe is particularly liable to attack milch-cows and young cattle in the ſpring ſeaſon, being occaſioned probably by their being kept through the winter in a low weak ſtate, and ſuddenly expoſed in the ſpring to the extreme coldneſs of the north and north-eaſterly winds, in low damp ſituations, or other ſimilar places.

In order to remove the diſorder, a ball of the ſame kind as that for horſes may be given for ſome days, until the ſoreneſs and ſtiffneſs begin to go off, when recourſe ſhould be had to ſuch powders or balls as thoſe recommended below, given in a hornful or two of warm ale.

The powder of gum guaiacum, in the quantity of about an ounce, with an ounce and a half of Æthiop's mineral, or ſulphuretted quickſilver, and two ounces of the grains of paradiſe, in fine powder: or, camphor in the proportion of about a drachm and a half, rubbed with a few drops of the ſpirit of wine, to which may be added guaiacum and Peruvian bark in fine powder, of each about an ounce and a half, warm ſeeds in powder three ounces, and treacle or honey two or three ounces, to form a ſort of ball.

The drinks of this ſort may be continued occaſionally for ſome time. And much utility may at firſt be derived from the uſe of a comfortable houſe of ſome kind or other for containing the animals, and afterwards by their being turned into dry warm paſtures, when the ſeaſon admits.

The rubbing of the ſwellings in the joints with ſtrong camphorated turpentine embrocations, as frequently practiſed, is moſtly improper, ſometimes injurious, and always hazardous.

Where the diſeaſe changes to, or puts on the appearance of a more inflammatory nature, as that of the acute rheumatic kind, with fever, pain, and tumefaction of or about the joints, it may be on ſome occaſions neceſſary to reſort to remedies of the camphor kind, with calomel, and a ſmall proportion of opium, giving at the ſame time ſome ſort of active opening or purging medicines. The above cordial ſtrengthening bark-powdery remedy will afterwards, for the moſt part, be of great utility.

STAG-*Horn Tree*, in *Gardening*. See RHUS.

STAG-*Worms*, in *Natural Hiſtory*, a name given to a ſpecies of worms produced from the eggs of a fly, and lodged in a very ſtrange place behind, and under the palate of the ſtag, or deer's mouth.

They are always found in great numbers together, and are contained in fleſhy bags, which are placed as the almonds of the ears in the human ſpecies. The huntſmen are well acquainted with theſe worms, and are of opinion that they are the cauſe of the falling off of the creature's horns; they eat their way to theſe, according to their opinion, through the proper parts of the head, and then gnawing them round at the roots, they are forced to fall, like a tree that is ſawed off at the bottom. This, however, is a vulgar error.

M. Reaumur has abundantly proved, that theſe worms never attempt ſo ſtrange a paſſage; they always remain where they are firſt found till they are in a ſtate to change into the flies to whoſe eggs they owe their origin, and whoſe forms they are at length to aſſume. Reaumur's Hiſt. Inſ. vol. ix. p. 8.

STAGE, in the *Modern Drama*, the place of action and repreſentation; included between the pit and the ſcenes.

The ſtage anſwers to the proſcenium or pulpitum of the ancient theatre.

For an account of the Engliſh ſtage, ſee MYSTERY, PLAYHOUSE, and SCENE. See alſo DRAMATIC *Machinery*, and SCENOGRAPHY.

Unlicenſed ſtage-plays are deemed public nuiſances, and may, upon indictment, be ſuppreſſed and fined.

STAGE, *Laws of the*, are the rules and decorums to be obſerved, with regard to the economy and conduct of a dramatic performance to be exhibited on the ſtage. Theſe relate, principally, to the unities, the diſpoſition of the acts and ſcenes, the unravelling, &c.

STAGE alſo denotes a certain diſtance to which ſtuff is to be wheeled, at ſtated prices *per* cubic yard: the uſual ſtage is an interval of 20 yards; but on very ſteep or quite level wheeling, they are ſometimes reckoned 15 yards, and in other caſes 25 yards.

STAGE *Iſland*, in *Geography*, a ſmall American iſland, near the coaſt of Maine, not far from Caſco bay, remarkable for being the firſt land inhabited by Europeans in New England. It is not now uninhabited.

STAGEBORG, a town of Sweden, in Eaſt Gothland; 15 miles S.E. of Nordkioping.

STAGGARD, among *Sportſmen*, a male deer only four years old.

STAGGERS, among *Farriers*, a diſeaſe of horſes, which has ſometimes been denominated *apoplexy* (which ſee), and which conſiſts of a giddineſs in the head, and which, in ſome caſes, is indicated by madneſs. Of this diſeaſe authors have deſcribed two ſpecies; *viz.* the *ſleepy*, and the *mad* ſtaggers. In the firſt ſpecies, the animal becomes inactive, and manifeſts a heavineſs of the eyes, and an inclination to ſleep, the head reſting in the manger; accompanied with coſtiveneſs, and other ſymptoms of fever. In the ſecond ſort of ſtaggers, the horſe, without indicating any previous ſigns of diſeaſe, falls down apparently deprived of all voluntary motion, with the eyes inſenſible to light, the breathing difficult, a great motion of the flanks, and a quick, full pulſe. In the mad ſtaggers the horſe often riſes, plunges violently in the ſtable, and again falls down in an inſenſible ſtate.

This diſeaſe is frequently occaſioned by turning out a horſe to graſs too ſoon, before he is well cold: where, by hanging down his head to feed, humours are generated, which oppreſſing the brain, are the proximate cauſe of this diſeaſe. Sometimes it comes by over-exerciſe in hot weather, which inflames the blood, &c. ſometimes by noiſome ſmells in the ſtable, exceſſive eating, &c. the rupture of a blood-veſſel, or external injuries on the head.

The ſigns of it are, dimneſs of ſight, reeling, and ſtaggering, watery eyes, &c. At length, through extreme pain, he beats his head againſt the wall, thruſts it into the litter, riſes and lies down with fury, &c.

The moſt approved remedy for this diſtemper is derived from the following treatment. Begin with copious bleeding from a large orifice in the neck-vein, and repeat the operation, if the ſtrength of the horſe admit of it, and the ſymptoms of the diſeaſe require it. After bleeding adminiſter a ball, prepared of two drachms of calomel, an ounce of Barbadoes aloes in powder, two drachms of ginger, and a ſufficient quantity of honey. Apply alſo a glyſter, prepared by mixing three quarts of oatmeal gruel, three ounces of common ſalt, and half a pint of olive oil. If the diſeaſe continue after this treatment, put a rowel under the jaw, and another in the cheſt; applying alſo, behind the ear, ſome bliſtering liniment: let the horſe be ſupported at the ſame time by maſhes, or if he refuſe theſe, by gruel in the quantity of two or three quarts, frequently given. After opening the bowels ſufficiently, let the following fever-powder be given: *viz.* one drachm of pulverized camphor, a ſcruple of antimonial powder, and ſix drachms of powdered nitre, all well mixed. When the ſymptoms are relieved, maſhes of bran or oatmeal may be occaſionally given, with a ſmall quantity of corn: hay ſhould be ſparingly allowed. Omit the powders, and give the following reſtorative ball every morning, till the horſe recovers ſtrength, taking care to keep his bowels open by maſhes: the ball is prepared of Peruvian bark and gentian, in powder, of each $\frac{1}{12}$th of an ounce; two drachms of ginger, one drachm of vitriolated iron, and a ſufficient quantity of honey. The rowel under the jaw ſhould be continued at leaſt a fortnight after the diſeaſe has been removed. Attention ſhould afterwards be obſerved with regard to the kind or quantity of food, the exerciſe and ſtable treatment.

Horſes are ſubject to convulſions and ſtaggers, ariſing from a retention of the dung and aliment; which are indicated by ſwoln eyes, reeling and tottering motion, ſhort breath and cough, and irregular motion of the flanks; averſeneſs from lying down, coſtiveneſs, indiſpoſition to ſtale, and dark-coloured urine; and ſometimes jaundice. Gibſon directs the dung to be raked out by the hand from the rectum, which dung is generally hard, in ſmall balls of a blackiſh colour, without moiſture. After this operation, adminiſter plenty of emollient oily glyſters of marſhmallows, or pot liquor, water gruel or water; adding to three pints or two quarts of the liquor a pint of linſeed-oil, and half a pound of treacle; which ſhould be given milk-warm, and repeated every day, till the dung comes away with eaſe, and in a ſoft ſtate: accompanying this medical treatment with diet of the beſt hay, ſcalded bran or chaff, or boiled barley. When the dung comes away with facility, and in great abundance, the following gentle lenitive purge may be given; *viz.* lenitive electuary and cream of tartar, of each four ounces, and two ounces of common ſugar, mixed in a pint and half of hot ale; to which, when the tartar is diſſolved, add the ſugar, and laſt of all the lenitive electuary. Let this be given in the morning, upon an empty ſtomach, blood-warm; and repeated three or four times, with a reſpite of two or three days between the draughts, keeping the horſe to an opening diet, with proper exerciſe, till he recovers his uſual vigour.

Mr. Boyle mentions a cure of this diſeaſe in horſes, by rubbing their gums with the coach-whip till they bleed. Works, Abr. vol. i. p. 88.

STAGGERS, a diſeaſe in ſheep, in which they are moſtly conſidered as extremely liable to move or turn themſelves about in a quick manner.

The remedy for this diſorder was formerly to drive them to a change of grounds often, to keep the grounds from tainting. And it has been noticed by Liſle, that thoſe lambs which die of the ſtaggers do not die till they begin to eat graſs, and of thoſe the fineſt and luſtieſt; whence he concludes, that it is not the cold weather alone that brings ſtaggers, but their feeding on cold watery graſs in the months of March and April. The diſeaſe was much prevented by the early folding of the lambs. See GID.

The diſeaſe moſtly appears in the autumn, and is ſaid to be produced by a variety of cauſes; ſuch as improper food, the leaves of the oak-tree, on account of their aſtringent quality, cobwebs beſprinkled with dew, and different others. And it probably often proceeds from local affections, and water in the brain. Some have likewiſe ſuppoſed that it ariſes from the operation of a poiſonous graſs, the *lolium temulentum*, which is alone met with in thoſe ſituations of Scotland where the ſtaggers in ſheep prevail. But what effect ſuch caſes have on the brain, to produce or cauſe ſuch a diſeaſe, is not pretended to be explained.

Where this diſeaſe continues for any length of time in the ſame ſheep, it is liable to become fatal.

The change of paſture is ſuppoſed to be the only effectual remedy in ſuch caſes, but the uſe of calomel and bark may often be found of material advantage, as well as other means which have a tendency to remove water from the brain.

STAGGERS is alſo a diſeaſe in neat cattle, which is often very troubleſome and unpleaſant in its conſequences and management. The principal ſeats of the diſorder would ſeem to be the head and the ſtomach, which naturally ſympathize with each other. It may proceed from a variety of different cauſes, as improper and inſufficient feeding, too much expoſure to cold, drinking too largely of very cold water, under particular circumſtances, water and local affections of different kinds in the brain and parts about it, and many others of the ſame nature.

It is moſt liable to attack ſuch cattle as have been poorly fed, or ſtarved in the winter ſeaſon, on their being firſt turned out upon good paſtures in the early ſpring; but it not unfrequently happens to other cattle which have been regularly fed. It likewiſe occurs in very different ſtates and degrees of violence, according to the circumſtances and habits of body of the animals. And it occaſionally takes place in calves, and other young ſtock of this ſort.

The diſeaſe ſhews itſelf by the reeling, wavering, ſtaggering, and imperfect gait of the animal; by the heavy, dull, and ſluggiſh motion and appearance of it; and an inclination to become drowſy, and the reſting or reclining of the head upon any convenient place near it.

It ſometimes, however, puts on a more local inflammatory appearance, in which caſes the beaſts have commonly a leſs heavy drowſy diſpoſition, with more of the wild raving or raging tendency and quality in their aſpects and diſpoſitions.

In the former of theſe ſtates, the diſeaſe may be attempted to be removed by the giving of calomel in pretty large doſes, as a drachm or more to a large beaſt, two or three times in the courſe of the week, and powders compoſed of camphor rubbed with a few drops of ſpirit of wine, in the quantity of about two drachms. Common nitre, or ſaltpetre in powder, two ounces and a half; and the roots of rhubarb in powder, or ſome other ſimilar matter, from one to two ounces and upwards, in the intervals between the doſes of calomel. The beaſt, during the time, ſhould be kept moderately warm, and have good hay and warm maſhes occaſionally given to it, preſerving it as much as poſſible in a temperate ſtate in every reſpect.

In the latter ſtate it may ſometimes be neceſſary to take away blood in proportion to the ſize and ſtrength of the beaſts, as from one to two or three quarts; after which, the bowels may be well opened by the uſe of pretty ſtrong purgatives of the ſaline kind; then, where there is much fever of the inflammatory kind attending the diſeaſe, a ball compoſed of tartarized antimony, in the quantity of from half to a whole drachm, with about two drachms of camphor rubbed as above, and from a drachm and a half to two drachms of prepared ammonia in powder, made up with a little treacle, may be given in a hornful or two of warm oatmeal gruel, once or oftener in the day to the beaſts, until it diſappears. In tedious caſes of this ſort, with much affection of the head, great relief may ſometimes be gained by the application of ſtrong bliſters about the head, or the rubbing of the parts near and upon it, and on the ſides of the neck, with ſtrong ointment of the bliſtering kind, after the hair has been well clipped off and removed from them.

Afterwards it will only be neceſſary to let the beaſts have a ſtrengthening cordial drink or two, and the uſe of a good dry paſture, when the ſeaſon will admit of it.

STAGGERWORT, in *Agriculture*. See RAGWORT.

STAGIRA, or STAGIRUS, in *Ancient Geography*, a town of Macedonia, in the vicinity of mount Athos, upon the Strymonic gulf, between Amphipolis on the north, and Acanthus on the ſouth. This town was the native place of Ariſtotle, hence called the Stagirite.

STAGNANT *Watery Land*. See WATERY *Land*.

STAGNO, in *Geography*, a ſea-port town of the republic of Raguſa, on the Adriatic, the ſee of a biſhop, ſuffragan of Raguſa: about a mile from the town is a fortreſs, called "Stagno Piccolo," or Little Stagno; 30 miles N.W. of Raguſa. N. lat. 43° 30′. E. long. 17° 59′.

STAGONIAS, a word uſed by the old authors to expreſs that ſort of male frankincenſe which is in round drops, and very clear and fine.

STAGONIUS, a name ſometimes given to ſtorax.

STAGS, in *Geography*. Several rocks on the coaſt of Ireland are ſo called; as, the Stags on the ſouth-eaſt entrance of Cork harbour, near Roches tower, where a lighthouſe is erecting; the Stags of Caſtlehaven, ſouth of Toehead, county of Cork; and the Stags of Broadhaven, north of Binwy-head, on the Mayo coaſt.

STAHL, GEORGE ERNEST, in *Biography*, a celebrated phyſician and chemiſt, was born at Anſpach, in Franconia, in October 1660. He ſtudied medicine at the univerſity of Jena, and laid the foundation of his fame, immediately after his graduation in 1684, by commencing a courſe of private lectures among the ſtudents of that place. His advancing reputation procured for him the appointment of phyſician in ordinary to the duke of Saxe-Weimar in 1687. On the eſtabliſhment of the univerſity at Halle, in 1694, Frederic Hoffmann, with his accuſtomed liberality, ſolicited the appointment of a medical profeſſorſhip for Stahl, who accepted the office, and became the rival of that diſtinguiſhed phyſician as a teacher of medical ſyſtems, but not in the exerciſe of candour and liberality towards his colleagues. Stahl was conſcious of poſſeſſing conſiderable mental powers, and paid little reſpect to the opinions of others; and he became the leader of a ſect or ſchool of phyſicians, in oppoſition to the mechanical theoriſts, in which he was followed by many eminent perſons, not only in Germany, but in other countries, as by Perrault in France, Gaubius in Holland, Porterfield and Simpſon in Scotland, and by Nichols and Mead in England, notwithſtanding the very fanciful nature of the hypotheſis on which his ſyſtem was founded. The "Conſpectus Medicinæ" of Juncker was publiſhed to illuſtrate his doctrines in Germany; and a ſuccinct account of the ſyſtem was given by Dr. Nichols, in his work "De Animâ Medicâ," in this country.

Phyſicians had always remarked a certain power in the animal body of reſiſting injuries and correcting ſome of its diſorders, which they had called *nature*, and *vis medicatrix naturæ*, and Van Helmont had already aſcribed ſome degree of intelligence to this power. But it remained for Stahl to refer this power entirely to the *rational ſoul*, which, he affirmed, not only originally formed the body, but is the ſole cauſe of its motions, in the conſtant excitement of which life conſiſts. For he maintained that the ſoul abhors the diſſolution of its body, and therefore excites and directs all its motions, the vital and involuntary as well as the voluntary motions, to prevent that diſſolution, by obviating putrefaction, and expelling the corrupted humours by various appropriate organs or excretories; in a word, that all the functions of the body are entirely directed by the mind, which intelligently perceives the tendency of all impreſſions, external and internal, made upon the body, and excites ſuch motions as may favour the beneficial, and obviate the injurious influence of all cauſes acting upon it. Whence he farther contended, that diſeaſes, ſuch as fevers and ſpaſmodic affections, were in fact the motions voluntarily excited by the rational ſoul, for the purpoſe of opening emunctories, and expelling ſome offending cauſe. Generally ſpeaking, therefore, it was maintained, that diſeaſes were ſalutary efforts of the preſiding ſoul, and were to be aſſiſted, and not interrupted, by the interference of art: yet it was ſomehow admitted, that the mind, from ſurpriſe, fear, or deſpair, occaſioned by too ſudden or vehement impreſſions made upon it, occaſionally excited adverſe motions, which it was right to moderate. Independently of the viſionary character of this hypotheſis, it was juſtly deprecated as leading phyſicians to neglect the uſe of remedies, or to uſe only the moſt inert and frivolous ones; and alſo to ſet little value upon the collateral ſtudies of medical ſcience, even upon anatomical reſearches, which Stahl maintained had little or no reference to the art of healing. And, in fact, both he and his followers, truſting principally to the attention and wiſdom of nature, adopted that inactive mode of *curing by expectation*, la médecine expectante, as the French have called it; they zealouſly oppoſed the uſe of ſome of the moſt efficacious remedies, ſuch as opium, cinchona, and mercury; and were extremely reſerved, even in the uſe of general evacuants, ſuch as bleeding, vomiting, &c. although their ſyſtem led them to refer almoſt all the diſturbances of the motions of the ſyſtem to a plethora, or too great abundance of the blood. This hypotheſis was maintained by Stahl in ſeveral publications, with much ability and ingenuity; and it continued to influence a great number of intelligent phyſicians for a long time. His principal medical work, in which his ſyſtem is diſplayed in its moſt matured form, is entitled "Theoria Medica vera, Phyſiologiam et Pathologiam ſiſtens," printed at Halle in 1708.

The merits of Stahl as a chemical philoſopher are of a much higher character; and the ſchool which he founded in this ſcience, after extending its influence long and univerſally among thoſe who purſued the ſame inquiries, has only been ſuperſeded of late by farther diſcoveries. He was the inventor of the celebrated theory of *phlogiſton*, which appeared to explain the phenomena of combuſtion and inflammability, and was received every where with high applauſe, and which, in fact, occaſioned Germany to become the great ſchool of chemiſtry. It cannot be denied, indeed, although later experiments have ſubverted the groundwork, that this hypotheſis tended greatly to ſimplify the ideas, and perfect the operations of chemiſts, and entitled its author to a high rank amongſt the improvers of ſcience. His principal chemical work was entitled, "Fundamenta Chymiæ dogmaticæ et experimentalis," firſt printed in 1729, and ſeveral times reprinted: but before that period he had publiſhed ſeveral other works on this ſubject, ſuch as "Diſſertationes de Metallurgiæ et Docimaſtiæ Fundamentis," 1697; and, in the ſame year, "Experimenta et Obſervationes 300 Chymicæ et Phyſicæ," in which work he principally advanced his doctrine of phlogiſton. He alſo publiſhed in the German language ſome eſſays "On Sulphur," and "On Salts."

Stahl was elected a member of the Academy Naturæ Curioſorum in 1700. He was called to viſit Frederic William, king of Pruſſia, at Berlin, in 1716; and afterwards returned ſeveral times to that capital, where his reputation was very high, and where at length he was attacked with a fatal diſeaſe, in 1734, in the ſeventy-fourth year of his age. See Eloy Dict. Hiſt. de la Médecine. Gen. Biog. Cullen's Firſt Lines. *Pref.* And Hoffmann's eſſay, "De Differentiâ Doctrinæ Stahlianæ et Hoffmannianæ."

STAIDENFELD, in *Geography*, a town of the duchy of Wurzburg; 4 miles S. of Schweinfurt.

STAIN, a town of the county of Tyrol; 2 miles S.W. of Meran.—Alſo, a town of Auſtria, on the Danube, conſiſting almoſt wholly of one ſtreet, and containing two churches. It is near Crems, and governed by the ſame magiſtrates. It is joined by a long bridge with Mautern, on the other ſide of the Danube; 32 miles W.N.W. of Vienna. —Alſo, a town of Auſtria; 2 miles N. of Steyr.

STAIN. See STEIN.

STAINABRUNN, a town of Auſtria; 6 miles W.S.W. of Ehrnſprunn.

STAINBACH, a town of Auſtria, on the Teichel; 6 miles S. of Steyr.

STAINER, JACOB, in *Biography*, a German maker of violins of the moſt ſprightly and brilliant tone. His ſignature, paſted on the inſide of the back, is the following; "Jacobus Stainer, in Abiam prope Œnopontum, 1647." Œnopons is the Latin name of Inſpruck in Germany, the chief city of Tyrol. Theſe violins, ſince ſolos have been laid aſide, have loſt ſomewhat of their former favour, and the Amati and Straduarii violins of Cremona, which are of a more full and rich tone, are preferred for leading a band, playing modern ſymphonies, and ſolo concertos *à grande orcheſtra*.

STAINES, or STANES, in *Geography*, a market-town in the hundred of Spelthorne, and county of Middleſex, England, is ſeated on the northern banks of the river Thames, over which there is a ſtrong timber bridge at this place, connecting the counties of Surrey and Middleſex. It is ſixteen miles from Hyde-Park corner, and moſt of its houſes extend along the ſides of the great weſtern road; but the pariſh church, with a few buildings, are ſituated nearly half a mile N.W. of the chief maſs of building. The pariſh conſiſts of 748 acres 16 perches of cultivated land, with 666 acres 1 rood and 20 perches of arable land. On a ſtratum of loam is a ſoil of fine black mould, and gravel is found in ſome places. According to the population report of 1811, this pariſh contained 355 houſes, and 2042 inhabitants.

In old records Staines was written *Stana*, a Saxon word for a ſtone; and Camden ſuppoſes that the name was derived from a ſtone, which was fixed in, or on the bank of the river here, to denote the extent of the juriſdiction of the city of London over the Thames, weſtward. A ſtone, bearing the date of 1280, on the margin of the water near the church, is ſtill preſerved here. An annual fair of four days was granted in the year 1228 to the abbot and convent of Weſtminſter, and is ſtill continued: a weekly market is held on Fridays. The civil government of the town is veſted in two conſtables and four headboroughs. Staines bridge appears to have been one of the moſt ancient in the country; ſo far back as the year 1262, three oaks out of Windſor foreſt were granted for its repairs by Henry III.; and numerous grants of pontage, or temporary tolls for the ſame purpoſe, were made from time to time, in many of the ſubſequent reigns, as appears by the records in the Tower. Theſe tolls were confirmed and enforced by acts of parliament in 1509 and 1597. In 1791 an act was paſſed for building a new bridge, and allowing certain tolls to defray the expence of the building. Under this act a ſtone bridge, of three arches, was begun in Auguſt 1792, and opened in March 1797: but in conſequence of one of the piers giving way, the bridge was neceſſarily taken down. One of caſt-iron was next ſubſtituted, but this alſo failed, and the builders were obliged to ſupport it by wooden piles and frame-work. The bridge in its preſent ſtate was completed in 1807. The pariſh church conſiſts of a chancel, nave, and north aiſle, ſeparated by circular columns and pointed arches. The door of the chancel is of early Norman architecture. A ſquare embattled tower at the weſt end was built by Inigo Jones in 1631, as appears by an inſcription on the ſouth ſide. In an apartment under the gallery ſtaircaſe are two unburied coffins, covered with crimſon velvet, and richly embelliſhed, containing the bodies of Jeſſie Aſpaſia, wife of F. W. Campbell, eſq. and of her brother, H. Caulfield, eſq.; the former died in 1812, the latter 1808. The Quakers, Anabaptiſts, and Methodiſts, have each a meeting-houſe in this town. A ſchool on the Lancaſtrian principle of education has been recently eſtabliſhed, and is ſupported by voluntary contribution; a convenient building has been erected for this purpoſe. Lyſons's Middleſex Pariſhes, 4to. 1800. Beauties of England and Wales, vol. x. Middleſex. By J. N. Brewer.

STAINHOF, a town of Auſtria; 3 miles S.W. of Vienna.

STAINKIRCHEN, in *Geography,* a town of Auſtria; 4 miles N. of Schwanaſtadt.

STAINS, a town of France, in the department of Paris; 6 miles N. of Paris.—Alſo, a lake of Pruſſia, in Natangen; 48 miles S.E. of Konigſberg.

STAINTZ, a town of the duchy of Stiria; 10 miles S.E. of Voitſberg.

STAINVILLE, a town of France, in the department of the Meuſe; 7 miles S.E. of Bar-le-Duc.

STAJO, or Staja, in *Commerce,* a corn meaſure of Italy, equal at Florence to 4 quarti, 16 metadeli, or 32 mezzate. The moggio, which contains 8 ſacchi, or 24 ſtaja, is equal to about 16 Engliſh buſhels. Salt is meaſured by the ſtajo, which weighs 72 lbs. Florence weight, or 54 lbs. avoirdupois. The ſtajo of Corſica is equal to 6104 cubic inches, and 28.60 ſtajo = 10 Engliſh quarters. The ſtaji of Leghorn = 1501 cubic inches, and 114.60 ſtaji = 10 Engliſh quarters. The ſtaji of Lucca = 1472 cubic inches, and 116.85 ſtaji = 10 Engliſh quarters. The ſtaji of Milan = 1055 cubic inches, and 162.96 ſtaji = 10 Engliſh quarters. That of Modena = 4297, and 40 ſtaji = 10 Engliſh quarters. The ſtaji of Turin = 2388 cubic inches, and 73.56 ſtaji = 10 Engliſh quarters. The ſtaji of Venice = 4943 cubic inches, and 34.78 ſtaji = Engliſh quarters.

STAJOLUS, among the *Romans,* a meaſure of length, uſed in ſurveying land; it was equal to five palms and three-fourths of a palm.

STAIRCASE, an aſcent incloſed between walls, or a baluſtrade, conſiſting of ſtairs or ſteps, with landing-places and rails; ſerving to make a communication between the ſeveral ſtories of a houſe.

The dimenſions of ſtairs are differently aſſigned by different authors; in this however they agree, that they muſt not be more than ſix, nor leſs than four inches high; nor more than eighteen, nor leſs than twelve inches broad; nor more than ſixteen, nor leſs than ſix feet long each ſtair. But theſe meaſures have only regard to fine buildings, ordinary houſes are excepted; yet even in theſe, the ſtairs are not to exceed eight inches in height, nor be leſs than nine inches in breadth, nor three feet in length.

To reduce the dimenſions of ſtairs to ſome natural, or at leaſt geometrical ſtandard, Vitruvius borrows the proportions of the ſides of a right-angled triangle, which the ancient ſchool expreſſed by the numbers 3, 4, and 5. The firſt for the perpendicular height; the ſecond for the horizontal breadth; and the third for the whole ſlope or inclination, from the edge of one ſtair to that of another.

But this rule is ſet aſide, and with good reaſon, by the modern builders. For, on this principle, the lower the ſtairs, the narrower they muſt be; and ſtairs, for inſtance, four inches high (ſuch as we find mentioned by ancient architects), muſt be but five and one-third inches broad.

One rule to be regarded in the making of ſtairs is, that they be laid according to the Italian phraſe, *con un tantino da ſcarpa, i. e.* ſomewhat ſloping, or a little higheſt behind, that the foot may, as it were, both aſcend and deſcend at once; which, though obſerved by few, is found a ſecret and delicate deception of the pains in mounting.

The conſtruction of a complete ſtaircaſe is one of the moſt curious works in architecture. The common rules to be obſerved in it are as follow.

1. That it have a full free light to prevent accidents of ſlipping, falling, &c.

2. That the ſpace over head be large and airy, which the Italians call *un bel ſfocato,* good ventilation, becauſe a man ſpends much breath in mounting.

3. That the half paces, or landing-places, be conveniently diſtributed for repoſing in the way.

4. That to prevent rencounters, &c. the ſtaircaſe be not too narrow; but this laſt is to be regulated by the quality of the building.

5. That care be taken in placing the ſtaircaſe, ſo that the ſtairs may be diſtributed, without prejudice to the reſt of the building.

The kinds of ſtaircaſes are various: in ſome, the ſtairs are *ſtraight,* in others *winding,* in others both ways, or *mixed.*

Again, of *ſtraight* ſtairs, called alſo *fliers,* ſome fly directly forwards; others are ſquare; others triangular; and others are called *French flights.*

Of *winding* ſtairs, called alſo *ſpiral,* or *cockle-ſtairs,* ſome are ſquare, ſome circular, and ſome elliptical. And theſe, again, are various; ſome winding round a ſolid, and others round an open newel.

Laſtly, of *mixed* ſtairs, ſome are called *dog-legged;* others both wind about a ſolid newel, and fly about a ſquare open newel.

Stairs, *Straight,* are ſuch as always fly, that is, proceed in a right line, and never wind; whence their denomination.

Of theſe there are ſeveral kinds; as,

Direct fliers, or *plain fliers,* which proceed directly from one floor to another, without turning either to the right or left; theſe are ſeldom uſed, except for garret or cellar ſtairs.

Square fliers, which fly round the ſides of a ſquare newel, either ſolid or open, having at every corner of the newel a ſquare half ſtep, taking up one-fourth of a circle; ſo that they fly from one half ſtep to another, and the length of the ſtairs is perpendicular to the ſide of the newel.

Triangular fliers, which fly round by the ſides of a triangular newel, either ſolid or open, having at each corner of the newel a trapezial half ſtep, taking up two-thirds of a circle; ſo that they fly from one half ſtep to another; and their length is perpendicular to the ſide of the newel.

French fliers, which fly firſt directly forwards, till they come within the length of a ſtair of the wall; and then have a ſquare half pace, from which you immediately aſcend to another half pace, from which the ſtairs fly directly back again, parallel to their firſt flight.

Stairs, *Winding,* are ſuch as always wind, and never fly; of theſe there is great variety; as,

Circular winding ſtairs, of which there are four kinds, *viz.* ſuch as wind about a ſolid newel, the fore-edge of each being in a right line, pointing to the centre of the newel; commonly uſed in church-ſteeples, and great old houſes: ſuch as wind round an open newel, the fore-ſide of each being in a right line, pointing to the centre of the newel; as thoſe in the Monument, London: ſuch as wind round a ſolid newel, only the fore-ſide of each an arc of a circle, either concave or convex, pointing near to the circumference of the newel: and ſuch as reſemble the laſt in all other reſpects, ſave that they have an open newel. Any of theſe winding ſtairs take up leſs room than other kinds.

In ſtairs that wind round a ſolid newel, architects make the diameter of the newel either $\frac{3}{6}$; or $\frac{1}{4}$, or $\frac{1}{3}$, or $\frac{2}{7}$ of that of the ſtaircaſe, according as that is in bigneſs. If very ſmall, the newel is but $\frac{3}{8}$, and if large $\frac{3}{7}$, &c.

In ſtairs that wind round an open newel, Palladio orders the newel to be one half of the diameter of the ſtaircaſe; though there does not appear any reaſon why the newel here ſhould not be proportioned to the ſtaircaſe, as in the former.

As to the number of ſtairs in each revolution; Palladio orders, that, in a ſtaircaſe ſix or ſeven feet diameter, the ſtairs in each revolution be twelve; if the diameter be eight, the ſtairs to be ſixteen; if nine or ten, the ſtairs to be twenty; and if eighteen, to be twenty-four.

Elliptical winding ſtairs, of which there are two kinds; the one winding round a ſolid, the other round an open newel: they are much of the ſame nature as circular ſtairs, excepting that, in the one, the newel is a circle, and, in the other, an ellipſis.

Square winding ſtairs are ſuch as wind round a ſquare newel, either ſolid or open; the fore-ſide of each ſquare being in a right line, pointing to the centre of the newel.

Triangular winding ſtairs are ſuch as wind round a triangular newel; the fore-ſide of each being a right line, pointing to the centre of the newel.

Columniated winding ſtairs.—Palladio mentions a ſtaircaſe, in Pompey's portico at Rome, ſet on columns, ſo as that the light they receive from above, may diſtribute itſelf to all parts alike.

Double winding ſtairs.—Scamozzi mentions a ſtaircaſe in this form, made by Piedro del Bergo, and Jean Coffin, at Sciamberg, in France, in the king's palace. It is ſo contrived, as that two perſons, the one aſcending, and the other deſcending, ſhall never meet.

Dr. Grew deſcribes a model of this kind of ſtaircaſe, kept in the Muſeum of the Royal Society. The foot of one of the ſtaircaſes, he ſays, is oppoſite to that of the other; and both make a parallel aſcent, and within the ſame cylinder. The newel in the middle is hollow, and built with long apertures, to convey light from candles placed at the bottom, and on the ſides of the newel into both caſes.

Quadruple winding ſtairs.—Palladio mentions a ſtaircaſe of this form, in the caſtle of Chambor, near Bloys. It conſiſts of four ſtaircaſes, carried up together, having each its ſeveral entrance, and going up one over another, in ſuch manner, as that, being in the middle of the building, the four ſerve to lead to four apartments; ſo that the people of the one need not go up and down the ſtairs of the other; yet being open in the middle, they all ſee each other paſs.

Mixed ſtairs are ſuch as partly *fly*, and partly *wind*; whence ſome call them *fliers* and *winders*. Of theſe there are ſeveral kinds; as,

Dog-legged ſtairs, which firſt fly directly forwards, then wind a ſemicircle, and then fly directly backwards, parallel to that.

Square fliers and winders have a ſquare newel, either ſolid or open; and fly by the ſides of the newel, winding a quadrant of a circle at each corner.

Solid and open newelled fliers and winders are of two kinds; the one winds a quadrant of a circle about a ſolid newel; then flies by the ſide of a ſquare open newel; then winds again by the ſide of a ſolid newel; then flies again, and ſo alternately. The other flies firſt, then winds, and then flies again alternately.

STAIRING, in *Geography*, a town of Auſtria; four miles W. of Voglabruck.

STAIRS, in *Building*, the ſteps by which we aſcend and deſcend from one ſtory of a houſe to another. See Staircase.

STAITH is a ſtage or ſtrong wooden ſcaffold, to which coal-waggons are conducted by a rail-way, in order to ſhoot their contents into ſhips, boats, or carts.

STAKE, in *Agriculture*, a long piece of branch-wood, or ſtrong ſtaff or ſtick fixed upright in the ground, in making hedges, between which the bruſh-wood is laid and interwoven in the making of them.

Stake, the name of a ſmall anvil uſed by ſmiths; ſometimes it ſtands on a broad iron foot, on the work-bench, to be moved up and down occaſionally; and ſometimes it hath a ſtrong iron ſpike at the bottom, by which it is fixed to ſome place on the work-bench. Its uſe is to ſet ſmall and cold work ſtraight, by hammering it on the ſtake, or to cut and punch upon it with the cold chiſſel, or cold punch.

Stake *of a Plough*. The ſtake is an upright piece of wood, paſſing at its bottom through that link of the tow-chain which paſſes through the box of the plough, and at its upper end receiving the end of what is called the *bridle-chain*, which ties it to the crow-ſtaff, or if it be not long enough, a wyth, or cord, is uſed to tie it: it is alſo tied to it again, a little below the pillow of the plough, by another wyth or cord. See Plough, Pillow, Crow-staves, &c.

Stakes, in *Ancient Armoury*, were long and pointed at both ends, and uſed to protect the archers from the attacks of the enemy's horſe: theſe were planted in the earth, ſloping before them. In the firſt of Edward VI. three hundred and fifty of theſe were in the ſtores of the town of Berwick, under the article of archers' ſtakes: there were alſo at the ſame time eight bundles of archers' ſtakes in Pontefract caſtle.

Stake-*Heads*, in *Rope-making*, are poſts, about four feet long and four by three inches ſquare, with four wooden pins fixed in the upper ſide to keep the ſtrands aſunder. For lines they are about two feet long and three by two inches ſquare, and have ſix pins.

Stake-*Poſts*, are poſts of oak, about four feet high and twelve inches diameter, with a mortiſe-hole in each, for the ſtake-heads to go in and out, to keep the rope from the ground. They are placed about ten yards diſtant from each other, along the whole length of the rope-walk.

STAKING, *Pointing*, or *Sharpening Hop-poles*, the art and practice of rendering their bottom parts pointed and ſharp, in ſomewhat the manner of the common hedge-ſtake, in order that they may be ſet into the ground or ſoil in a firm and ready manner. See Hop, and Stacking *and Preſerving Hop-poles*.

STAL-*Boat*, a kind of fiſhing-boat mentioned 27 Eliz. c. 21.

STALACTAGNIA, in *Natural Hiſtory*, the name of a genus of ſpars. The word is derived from the Greek ϛαλακτος, *ſtillatitious*, or formed by dropping, and αγνος, *pure*.

The bodies of this genus are formed by the dropping of water from the roofs of ſubterranean caverns, and are the purer ſort of what are called by authors *ſtalactitæ*. They are cryſtalline ſparry bodies, formed into oblong conical figures, compoſed of various cruſts, and uſually found in form of icicles. Of this genus there are three known ſpecies. Hill.

STALACTITE, plural *Stalactites*, in *Mineralogy*, are the pendent protuberances from the roofs or ſides of caverns, formed by the depoſition of calcareous or other earths, from the water which percolates through rocks.

Some waters, that riſe from beds of limeſtone, are ſo overcharged with calcareous earth, as to form an incruſtation of ſtone round any ſubſtance that is immerſed in them for a ſhort time; of which we have well-known inſtances in the waters of Matlock, in Derbyſhire, and Knareſborough, in Yorkſhire: ſuch are called petrifying ſprings. It is by a ſimilar proceſs that ſtalactites are formed, by the water dropping from ſome projecting point and depoſiting a part of its contents; ſucceeding drops continue to enlarge the depoſition, which frequently aſſumes the form of an icicle, and is ſometimes of conſiderable ſize.

Stalactites form ſo rapidly in ſome caverns and mines as to cloſe up the entrance, and even fill up the excavation entirely. The depoſitions of calcareous earth formed on the floors of caverns, by the water which drops from the roof, are called *ſtalagmites*.

Though the formation of ſtalactites apparently depends on the mechanical depoſition of earthy matter, and may ſeem to admit of an eaſy explanation, there are ſome peculiarities of ſtructure in ſtalactitical maſſes which it is more difficult to account for.

In ſome ſtalactites we may obſerve a radiated diverging cryſtalline ſtructure; in others, the lamellar ſtructure of calcareous ſpar is obſervable when broken, and they divide into rhombs, or the regular primitive cryſtals of carbonate of lime. The progreſs from the radiated to the regular cryſtalline ſtructure may be ſeen in the ſame ſpecimen: thus it ſhould appear, that the particles of the ſtalactite, after they had been mechanically depoſited, and formed a ſolid, were capable of a certain degree of motion, which permitted their cryſtalline arrangement to proceed to its ultimate form, or the primitive rhomb. Some ſtalactites have occaſionally been found which were tubular; other ſtalactites, that are ſolid, are covered with minute cryſtals, and ſometimes are terminated by a knob, reſembling a muſhroom. Stalactites are not unfrequently formed under the arches of bridges, by the percolation of water through the mortar.

In the Geyſers, or boiling ſprings of Iceland and other parts of the world, ſiliceous ſtalactites and ſtalagmites are formed on the ſides of the rocks on which the water falls, or in the baſins which ſurround the ſprings. Theſe natural baſins are indeed entirely formed of ſiliceous depoſitions, and it has been aſcertained, that the waters contain a conſiderable portion of ſilex in ſolution.

The larger and more compact maſſes of ſtalactites are employed in ſtatuary. This ſubſtance was much uſed by the ancients, and called *alabaſtron* and *alabaſtrites*. The alabaſter of the moderns is more frequently gypſum, or ſulphate of lime.

The alabaſter from ſtalactite is ſometimes of a pure white, but this kind is not ſo durable as that which is of a light yellow colour, or veined. The iron, which is the colouring matter, communicates to the ſtone a great degree of hardneſs, and on this account the coloured alabaſter was more prized by the ancient ſculptors than the pure white. See STONE *for Statuary*.

STALACTITICAL, formed like ſtalactite.

STALACTOCIBDELA, in *Natural Hiſtory*, the name of a genus of ſpars. The word is derived from the Greek ϛαλακτος, *ſtillatitious*, or formed by the dropping of water, and κιβδηλος, *impure*.

The bodies of this genus are formed by the dropping of water from the roofs of ſubterranean caverns, and are the coarſer kinds of what authors have called ſtalactitæ. They are cryſtallino-terrene ſpars, formed into oblong bodies, and found hanging from the roofs of caverns and grottoes. Of this genus there are only two known ſpecies. Hill.

STALAGMITÆ. See STALACTITE and STALAGMOSCIERIA.

STALAGMITE, in *Mineralogy*, the depoſition of earthy matter, formed by drops of water on the floors of caverns. The word is derived from the Greek ϛαλαγμα, *a drop*. See STALACTITE.

STALAGMITIS, in *Botany*, ſo called by Murray, in the Göttingen Tranſactions, v. 9, from ϛαλαγμος, *a dropping*, or *diſtillation*, becauſe of the gum yielded by this tree.—Schreb. Gen. 729. Willd. Sp. Pl. v. 4. 980.—Claſs and order, *Polygamia Monoecia*, or rather *Polyadelphia Polyandria*. Nat. Ord. *Guttiferæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, deciduous, of four roundiſh, concave, coloured leaves, fleſhy in the middle, bordered; the two outermoſt coriaceous, ſmalleſt; the two innermoſt thinner and veiny. *Cor.* Petals four, obovate, rather coriaceous, fringed, ſpreading, larger than the calyx; the two oppoſite ones largeſt. *Stam.* Filaments about thirty, inſerted into a fleſhy quadrangular receptacle, club-ſhaped, abrupt, ſomewhat quadrangular, erect, the length of the corolla, united into five ſets; anthers erect, of two round lobes. *Piſt.* Germen ſuperior, globoſe; ſtyle erect, thick, ſhort; ſtigma of four inverſely heart-ſhaped, ſpreading, permanent lobes. *Peric.* Berry globoſe, of one cell, crowned with the ſtyle and ſtigma. *Seeds* three, oblong, obſcurely triangular, "terminated by a joint."

Some male flowers are interſperſed, in which there is no germen, only the thread-ſhaped rudiment of a ſtyle in ſome of them, with a prickly unequal imperfect ſtigma. Koenig obſerved the calyx to conſiſt occaſionally of ſix leaves, while the ſtigma was only three-cleft. Schreber doubted whether the ſtamens were always polyadelphous.

1. S. *cambogioides*. "Murray Comm. Goett. v. 9. 173." Willd. n. 1.—Native of Camboja and Ceylon. A middle-ſized *tree*, with oppoſite ſpreading *branches*. *Leaves* oppoſite, ovate, acute, entire, flat, coriaceous, rigid, dark-green, ſmooth on both ſides; occaſionally obovate. *Footſtalks* very ſhort. *Flowers* axillary or lateral, whorled; the male ones either intermixed with the others, or in a cluſter by themſelves. *Murray*. This tree appears nearly akin to the XANTHOCHYMUS of Roxburgh, ſee that article hereafter; Ait. Hort. Kew. v. 4. 420; yet we muſt preſume them to be different on account of the great authorities on which the latter depends.

STALAGMODIAUGIA, in *Natural Hiſtory*, the name of a genus of ſpars. The word is derived from the Greek ϛαλαϛμος, *a drop*, and διαυγης, *pellucid*. The bodies of this genus are the purer kinds of what authors call ſtalagmitæ, or drop-ſtones.

They are ſpars found in form of ſmall balls, each compoſed of numerous cruſts, and conſiderably pellucid and cryſtalline. Of this genus there are three known ſpecies. Hill.

STALAGMOS, a term uſed by authors to expreſs a diſtillation of rheum from the head.

STALAGMOSCIERIA, the name of a genus of ſpars. The word is derived from the Greek ϛαλαϛμος, *a drop*, and σκιερος, *opaque*, and expreſſes an opaque ſpar, which has received its form from the dropping of water.

The bodies of this genus are the coarſer kinds of what are called by authors ſtalagmitæ, and are ſmall round maſſes, compoſed of numerous thin cruſts, and of an opaque and coarſe ſtructure.

Of this genus we have only two known ſpecies. Hill.

Scotland affords a vaſt variety of the ſtalagmitæ. One the ſtaircaſe, according as that is in bigneſs. If very ſmall, the newel is but $\frac{3}{8}$, and if large $\frac{3}{7}$, &c.

In ſtairs that wind round an open newel, Palladio orders the newel to be one half of the diameter of the ſtaircaſe; though there does not appear any reaſon why the newel here ſhould not be proportioned to the ſtaircaſe, as in the former.

As to the number of ſtairs in each revolution; Palladio orders, that, in a ſtaircaſe ſix or ſeven feet diameter, the ſtairs in each revolution be twelve; if the diameter be eight, the ſtairs to be ſixteen; if nine or ten, the ſtairs to be twenty; and if eighteen, to be twenty-four.

Elliptical winding ſtairs, of which there are two kinds; the one winding round a ſolid, the other round an open newel: they are much of the ſame nature as circular ſtairs, excepting that, in the one, the newel is a circle, and, in the other, an ellipſis.

Square winding ſtairs are ſuch as wind round a ſquare newel, either ſolid or open; the fore-ſide of each ſquare being in a right line, pointing to the centre of the newel.

Triangular winding ſtairs are ſuch as wind round a triangular newel; the fore-ſide of each being a right line, pointing to the centre of the newel.

Columniated winding ſtairs.—Palladio mentions a ſtaircaſe, in Pompey's portico at Rome, ſet on columns, ſo as that the light they receive from above, may diſtribute itſelf to all parts alike.

Double winding ſtairs.—Scamozzi mentions a ſtaircaſe in this form, made by Piedro del Bergo, and Jean Coffin, at Sciamberg, in France, in the king's palace. It is ſo contrived, as that two perſons, the one aſcending, and the other deſcending, ſhall never meet.

Dr. Grew deſcribes a model of this kind of ſtaircaſe, kept in the Muſeum of the Royal Society. The foot of one of the ſtaircaſes, he ſays, is oppoſite to that of the other; and both make a parallel aſcent, and within the ſame cylinder. The newel in the middle is hollow, and built with long apertures, to convey light from candles placed at the bottom, and on the ſides of the newel into both caſes.

Quadruple winding ſtairs.—Palladio mentions a ſtaircaſe of this form, in the caſtle of Chambor, near Bloys. It conſiſts of four ſtaircaſes, carried up together, having each its ſeveral entrance, and going up one over another, in ſuch manner, as that, being in the middle of the building, the four ſerve to lead to four apartments; ſo that the people of the one need not go up and down the ſtairs of the other; yet being open in the middle, they all ſee each other paſs.

Mixed ſtairs are ſuch as partly *fly*, and partly *wind*; whence ſome call them *fliers* and *winders*. Of theſe there are ſeveral kinds; as,

Dog-legged ſtairs, which firſt fly directly forwards, then wind a ſemicircle, and then fly directly backwards, parallel to that.

Square fliers and winders have a ſquare newel, either ſolid or open; and fly by the ſides of the newel, winding a quadrant of a circle at each corner.

Solid and open newelled fliers and winders are of two kinds; the one winds a quadrant of a circle about a ſolid newel; then flies by the ſide of a ſquare open newel; then winds again by the ſide of a ſolid newel; then flies again, and ſo alternately. The other flies firſt, then winds, and then flies again alternately.

STAIRING, in *Geography*, a town of Auſtria; four miles W. of Voglabruck.

STAIRS, in *Building*, the ſteps by which we aſcend and deſcend from one ſtory of a houſe to another. See STAIRCASE.

STAITH is a ſtage or ſtrong wooden ſcaffold, to which coal-waggons are conducted by a rail-way, in order to ſhoot their contents into ſhips, boats, or carts.

STAKE, in *Agriculture*, a long piece of branch-wood, or ſtrong ſtaff or ſtick fixed upright in the ground, in making hedges, between which the bruſh-wood is laid and interwoven in the making of them.

STAKE, the name of a ſmall anvil uſed by ſmiths; ſometimes it ſtands on a broad iron foot, on the work-bench, to be moved up and down occaſionally; and ſometimes it hath a ſtrong iron ſpike at the bottom, by which it is fixed to ſome place on the work-bench. Its uſe is to ſet ſmall and cold work ſtraight, by hammering it on the ſtake, or to cut and punch upon it with the cold chiſſel, or cold punch.

STAKE *of a Plough*. The ſtake is an upright piece of wood, paſſing at its bottom through that link of the tow-chain which paſſes through the box of the plough, and at its upper end receiving the end of what is called the *bridle-chain*, which ties it to the crow-ſtaff, or if it be not long enough, a wyth, or cord, is uſed to tie it: it is alſo tied to it again, a little below the pillow of the plough, by another wyth or cord. See PLOUGH, PILLOW, CROW-STAVES, &c.

STAKES, in *Ancient Armoury*, were long and pointed at both ends, and uſed to protect the archers from the attacks of the enemy's horſe: theſe were planted in the earth, ſloping before them. In the firſt of Edward VI. three hundred and fifty of theſe were in the ſtores of the town of Berwick, under the article of archers' ſtakes: there were alſo at the ſame time eight bundles of archers' ſtakes in Pontefract caſtle.

STAKE-*Heads*, in *Rope-making*, are poſts, about four feet long and four by three inches ſquare, with four wooden pins fixed in the upper ſide to keep the ſtrands aſunder. For lines they are about two feet long and three by two inches ſquare, and have ſix pins.

STAKE-*Poſts*, are poſts of oak, about four feet high and twelve inches diameter, with a mortiſe-hole in each, for the ſtake-heads to go in and out, to keep the rope from the ground. They are placed about ten yards diſtant from each other, along the whole length of the rope-walk.

STAKING, *Pointing*, or *Sharpening Hop-poles*, the art and practice of rendering their bottom parts pointed and ſharp, in ſomewhat the manner of the common hedge-ſtake, in order that they may be ſet into the ground or ſoil in a firm and ready manner. See HOP, and STACKING *and Preſerving Hop-poles*.

STAL-*Boat*, a kind of fiſhing-boat mentioned 27 Eliz. c. 21.

STALACTAGNIA, in *Natural Hiſtory*, the name of a genus of ſpars. The word is derived from the Greek ϛαλακτος, *ſtillatitious*, or formed by dropping, and αγνος, *pure*.

The bodies of this genus are formed by the dropping of water from the roofs of ſubterranean caverns, and are the purer ſort of what are called by authors *ſtalactitæ*. They are cryſtalline ſparry bodies, formed into oblong conical figures, compoſed of various cruſts, and uſually found in form of icicles. Of this genus there are three known ſpecies. Hill.

STALACTITE, plural *Stalactites*, in *Mineralogy*, are the pendent protuberances from the roofs or ſides of caverns, formed by the depoſition of calcareous or other earths, from the water which percolates through rocks.

Some waters, that riſe from beds of limeſtone, are ſo overcharged with calcareous earth, as to form an incruſtation of ſtone round any ſubſtance that is immerſed in them for a ſhort time; of which we have well-known inſtances in the waters of Matlock, in Derbyſhire, and Knareſborough, in Yorkſhire: ſuch are called petrifying ſprings. It is by a ſimilar proceſs that ſtalactites are formed, by the water dropping from ſome projecting point and depoſiting a part of its contents; ſucceeding drops continue to enlarge the depoſition, which frequently aſſumes the form of an icicle, and is ſometimes of conſiderable ſize.

Stalactites form ſo rapidly in ſome caverns and mines as to cloſe up the entrance, and even fill up the excavation entirely. The depoſitions of calcareous earth formed on the floors of caverns, by the water which drops from the roof, are called *ſtalagmites*.

Though the formation of ſtalactites apparently depends on the mechanical depoſition of earthy matter, and may ſeem to admit of an eaſy explanation, there are ſome peculiarities of ſtructure in ſtalactitical maſſes which it is more difficult to account for.

In ſome ſtalactites we may obſerve a radiated diverging cryſtalline ſtructure; in others, the lamellar ſtructure of calcareous ſpar is obſervable when broken, and they divide into rhombs, or the regular primitive cryſtals of carbonate of lime. The progreſs from the radiated to the regular cryſtalline ſtructure may be ſeen in the ſame ſpecimen: thus it ſhould appear, that the particles of the ſtalactite, after they had been mechanically depoſited, and formed a ſolid, were capable of a certain degree of motion, which permitted their cryſtalline arrangement to proceed to its ultimate form, or the primitive rhomb. Some ſtalactites have occaſionally been found which were tubular; other ſtalactites, that are ſolid, are covered with minute cryſtals, and ſometimes are terminated by a knob, reſembling a muſhroom. Stalactites are not unfrequently formed under the arches of bridges, by the percolation of water through the mortar.

In the Geyſers, or boiling ſprings of Iceland and other parts of the world, ſiliceous ſtalactites and ſtalagmites are formed on the ſides of the rocks on which the water falls, or in the baſins which ſurround the ſprings. Theſe natural baſins are indeed entirely formed of ſiliceous depoſitions, and it has been aſcertained, that the waters contain a conſiderable portion of ſilex in ſolution.

The larger and more compact maſſes of ſtalactites are employed in ſtatuary. This ſubſtance was much uſed by the ancients, and called *alabaſtron* and *alabaſtrites*. The alabaſter of the moderns is more frequently gypſum, or ſulphate of lime.

The alabaſter from ſtalactite is ſometimes of a pure white, but this kind is not ſo durable as that which is of a light yellow colour, or veined. The iron, which is the colouring matter, communicates to the ſtone a great degree of hardneſs, and on this account the coloured alabaſter was more prized by the ancient ſculptors than the pure white. See STONE *for Statuary.*

STALACTITICAL, formed like ſtalactite.

STALACTOCIBDELA, in *Natural Hiſtory*, the name of a genus of ſpars. The word is derived from the Greek ϛαλακτος, *ſtillatitious*, or formed by the dropping of water, and κιϐδηλος, *impure.*

The bodies of this genus are formed by the dropping of water from the roofs of ſubterranean caverns, and are the coarſer kinds of what authors have called ſtalactitæ. They are cryſtallino-terrene ſpars, formed into oblong bodies, and found hanging from the roofs of caverns and grottoes. Of this genus there are only two known ſpecies. Hill.

STALAGMITÆ. See STALACTITE and STALAGMOSCIERIA.

STALAGMITE, in *Mineralogy*, the depoſition of earthy matter, formed by drops of water on the floors of caverns. The word is derived from the Greek ϛαλαγμα, *a drop*. See STALACTITE.

STALAGMITIS, in *Botany*, ſo called by Murray, in the Göttingen Tranſactions, v. 9, from ϛαλαγμος, *a dropping*, or *diſtillation*, becauſe of the gum yielded by this tree.—Schreb. Gen. 729. Willd. Sp. Pl. v. 4. 980.—Claſs and order, *Polygamia Monoecia*, or rather *Polyadelphia Polyandria.* Nat. Ord. *Guttiferæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, deciduous, of four roundiſh, concave, coloured leaves, fleſhy in the middle, bordered; the two outermoſt coriaceous, ſmalleſt; the two innermoſt thinner and veiny. *Cor.* Petals four, obovate, rather coriaceous, fringed, ſpreading, larger than the calyx; the two oppoſite ones largeſt. *Stam.* Filaments about thirty, inſerted into a fleſhy quadrangular receptacle, club-ſhaped, abrupt, ſomewhat quadrangular, erect, the length of the corolla, united into five ſets; anthers erect, of two round lobes. *Piſt.* Germen ſuperior, globoſe; ſtyle erect, thick, ſhort; ſtigma of four inverſely heart-ſhaped, ſpreading, permanent lobes. *Peric.* Berry globoſe, of one cell, crowned with the ſtyle and ſtigma. *Seeds* three, oblong, obſcurely triangular, "terminated by a joint."

Some male flowers are interſperſed, in which there is no germen, only the thread-ſhaped rudiment of a ſtyle in ſome of them, with a prickly unequal imperfect ſtigma. Koenig obſerved the calyx to conſiſt occaſionally of ſix leaves, while the ſtigma was only three-cleft. Schreber doubted whether the ſtamens were always polyadelphous.

1. S. *cambogioides.* "Murray Comm. Goett. v. 9. 173." Willd. n. 1.—Native of Camboja and Ceylon. A middle-ſized *tree*, with oppoſite ſpreading *branches*. *Leaves* oppoſite, ovate, acute, entire, flat, coriaceous, rigid, dark-green, ſmooth on both ſides; occaſionally obovate. *Footſtalks* very ſhort. *Flowers* axillary or lateral, whorled; the male ones either intermixed with the others, or in a cluſter by themſelves. *Murray.* This tree appears nearly akin to the XANTHOCHYMUS of Roxburgh, ſee that article hereafter; Ait. Hort. Kew. v. 4. 420; yet we muſt preſume them to be different on account of the great authorities on which the latter depends.

STALAGMODIAUGIA, in *Natural Hiſtory*, the name of a genus of ſpars. The word is derived from the Greek ϛαλαγμος, *a drop*, and διαυγης, *pellucid*. The bodies of this genus are the purer kinds of what authors call ſtalagmitæ, or drop-ſtones.

They are ſpars found in form of ſmall balls, each compoſed of numerous cruſts, and conſiderably pellucid and cryſtalline. Of this genus there are three known ſpecies. Hill.

STALAGMOS, a term uſed by authors to expreſs a diſtillation of rheum from the head.

STALAGMOSCIERIA, the name of a genus of ſpars. The word is derived from the Greek ϛαλαγμος, *a drop*, and σκιερος, *opaque*, and expreſſes an opaque ſpar, which has received its form from the dropping of water.

The bodies of this genus are the coarſer kinds of what are called by authors ſtalagmitæ, and are ſmall round maſſes, compoſed of numerous thin cruſts, and of an opaque and coarſe ſtructure.

Of this genus we have only two known ſpecies. Hill.

Scotland affords a vaſt variety of the ſtalagmitæ. One cave, about eight miles diſtant from Aberdeen, on the ſea-ſide, has its whole roof cruſted over with ſtalactitæ, of a foot in length, hanging down like the fringe of a bed; the floor alſo is as deeply covered with congeries of ſtalagmitæ; the upper coat, both of theſe and the ſtalactites, is of a ſea-colour, but the inner parts are as white as ſal prunellæ; the water which drops from theſe is of a very peculiar nature, for it is ſo acrimonious, that if it touch the ſkin but ever ſo ſlightly, it makes it ſmart. Near this cave there is another hollow rock, in which the ſtalactitæ make a very beautiful figure: they are all formed into long and thick columns, and ſtand perpendicularly, ſo that they repreſent the pipes of an organ; when broken, they are all found to be hollow within. The rock, and all the ſtone thereabouts, is of the limeſtone kind.

STALBRIDGE, in *Geography*, a ſmall market-town in the hundred of Brownſhall, in the Sherbourne diviſion of Dorſetſhire, England, is ſituated near the banks of the river Stour, on the N. ſide of the county; 9 miles E. from Sherbourne, and 113 miles W.S.W. from London. The manor was anciently the property of the abbey of Sherbourne: after the diſſolution of monaſteries, Edward VI. granted it to the duke of Somerſet; on his death it paſſed to the Audley family, and afterwards to Richard, earl of Corke; he bequeathed it to his ſon Robert Boyle, who reſided here many years; and his firſt chemical experiments were made in the manor-houſe in 1647. Peter Walter, eſq. clerk of the peace for Middleſex, afterwards purchaſed the manor, and in his family it has ſince continued. The town of Stalbridge, and the greater part of the pariſh, are ſeated on a rocky ſtratum, whence the vicinity is ſupplied with ſtone for building and other uſes: the principal manufactory here is that of ſtockings, which is carried on to a very conſiderable extent. Two fairs are held annually, and a market weekly, on Thurſdays. In the population report of 1811, the number of houſes in this pariſh is ſtated to be 141, of inhabitants 890.

In the centre of the town is a ſtone croſs, which, including the baſe, is thirty feet high. At the top is a ſquare block, with four niches; thoſe on the eaſt and weſt fronts have the Crucifixion, with the Virgin, and St. John. On this block ſtood a croſs; and from the top of the free-ſtone of the pyramid to the hole in which this croſs was fixed, the height is ten feet. At the bottom of this block are ſeveral coats of arms; one of them ſeems a chevron or feſs between three roſes or eſcallops. The pyramid itſelf is twelve feet high, and all the angles are fluted. On one ſide of it is a defaced figure of our Saviour, with the lamb at his feet. The four ſides of the baſe are adorned with reliefs, one of which ſeems to repreſent the reſurrection of Chriſt, who holds a croſs in his hand. The whole ſtands on three octagonal flights of ſteps, each diminiſhing in the aſcent. Hutchins's Hiſtory of Dorſetſhire, 3 vols. fol. 1796, &c.

STALE, in *Agriculture*, a term uſed provincially to ſignify the handle of any thing or kind of tool, as a fork-ſtale, &c.

Stale, in *Rural Economy*, a term applied to the urine of animals: the ſtale of horſes and ſome other animals ſhould be carefully preſerved for uſe in the way of manure. See Urine.

Stale alſo denotes a living fowl, put in a place to allure and bring others where they may be taken. See Decoy.

For want of theſe, a bird, ſhot, his entrails taken out, and dried in an oven, in his feathers, with a ſtick thruſt through to keep it in a convenient poſture, may ſerve as well as a live one.

Stale *Furrow*, in *Agriculture*, a term applied to a furrow which has been long turned up, or in which the ſlice has been for ſome time expoſed to the weather, in contradiſtinction to that which is newly formed, or in a freſh ſtate. See Sowing.

Stale *Seeding*, the cuſtom or practice of ſeeding or ſowing land which has been long turned up, or in the ploughed ſtate. The practice, though common, and held in much eſteem with ſome in different places, ſhould probably never be had recourſe to, except in ſome caſes with wheat, as where a firm and ſolid bottom is required in conſequence of the too great friability or looſe powdery quality of the ſoil, as in putting that crop in after potatoes, in ſome inſtances, and other ſimilar products, which are apt to cauſe a very light ſtate of the mould or ſoil. On account of the convenience of breaking up the lay grounds during a part of the winter ſeaſon in ſome ſituations, ſtale ſeeding of the land has been practiſed, eſpecially with oats and ſome other ſorts of ſeed; but how far it has been found either beneficial or detrimental, has not yet perhaps been fairly put to the teſt of experiment. See Sowing.

Stale *Sowing*, in *Gardening*, the practice of ſowing or putting in ſome ſorts of ſeed into ground which has been dug up ſome time, and is in a ſtale condition. This is in ſome inſtances the caſe with peas, beans, and ſome other leguminous ſeeds, as well as thoſe of ſome other kinds; but it ought always to be as much as poſſible avoided. See Sowing *of Seeds*.

STALECKE, in *Geography*, a town of France, in the department of Mont Tonnerre; 1 mile N.N.W. of Bacarach.

STALIKON, a town of Switzerland, in the canton of Zurich; 6 miles S.W. of Zurich.

STALIMENE. See Lemnos.

STALING, a term uſed to ſignify the act of evacuating the urinary bladder in the horſe or mare, or other animal of the ſame kind. In team as well as other horſes, it is a humane and neceſſary practice to ſuffer them to void their urine at full leiſure, and to encourage them to it by *whiſtling*, or any other of the ſoothing methods which they may underſtand. The evacuation of urine is liable to interruption, profuſion, and to be diſeaſed from various cauſes, and thereby to produce much injury to the animals.

But neither team nor other horſes are much ſubject to ſtale blood, unleſs in caſes where they have ſuſtained ſome hurt, or been ſtrained in the loins or kidnies, and when ſome of the blood-veſſels about the neck of the bladder have been ruptured or burſt open, or in caſes of eroſion taking place there, or in the paſſage of the urine, by means of which ſome of the ſmaller and more minute veſſels of theſe parts may have been laid open, and ſend forth a bloody ſort of diſcharge; but when this laſt happens, it is moſtly very ſmall in quantity, and but of ſhort duration, commonly going off without any aſſiſtance in the way of medicine.

In caſes where the urine paſſes off in an intermixed bloody ſtate, or blood comes away in an almoſt pure or clear condition immediately after the ſtaling of the animal, the complaint may be removed, if the horſe is ſtrong, well fed, and in a full condition, by bleeding in a pretty plentiful manner, according to the ſize and ſtate of the animal; but if he be of the team hard wrought kind, and low in condition, it muſt be uſed in a much more ſparing way, and, in many inſtances, be wholly omitted. After bleeding, and in thoſe ſtates of the diſeaſe in which it is unneceſſary, the uſe of mild aſtringent opiate remedies may often be employed internally with great advantage; ſuch as the red reſtringent gum, in the quantity of two, three, or more drachms, according to circumſtances, in fine powder; oak-bark, or that of the Peruvian kind, in powder, two or three ounces; and powdered crude opium, from a ſcruple to about half a drachm; mixed and made up into a ball with a little honey or treacle, and given to the horſe once or oftener in the day, until the bloody ſtaling diſcharge goes off and wholly diſappears, which is aſcertained by the animal ſtaling in a free and perfect manner. Other ſimilar ſorts of aſtringent ſubſtances and barks may likewiſe be made uſe of with perhaps equal benefit, where theſe cannot be had, as well as ſome reſtringent tinctures, ſuch as thoſe of the above gummy matter and ſeveral others. All theſe remedies ſhould conſtantly be given in large quantities of ſome kinds of mucilaginous liquids, as the free uſe of ſuch ſubſtances is found to be highly beneficial in all caſes of this nature.

After ſuch complaints are wholly removed, the ſtrength of the animals may be reſtored by the giving of ſuch powdery ſubſtances as are directed below, in full quantities of oatmeal or other ſorts of gruel, as there may be occaſion. The powder of the root of gentian, and that of Peruvian bark, in the proportion of from one to two or more ounces; ginger in powder, one ounce or more; and ſometimes the ruſt, or the ſalt of ſteel powdered, in the quantity of about half an ounce of the former, and from one and a half to two drachms of the latter. The horſes ſhould likewiſe have a pretty free uſe of maſhes of different nouriſhing ſorts.

There is a profuſe ſort of ſtaling in horſes of the farm, team, and other kinds, which ſometimes conſtitutes and becomes a diſeaſe. See DIABETES.

STALK, among *Botaniſts*, that part of a plant which riſes immediately from the root, and which uſually ſupports the leaves, the flowers, and the fruit.

The term *ſtalk* is uſed on all occaſions; but in ſpeaking of the graſſes, and gramineous plants, the word *culm* is uſed in its place, to diſtinguiſh that peculiar kind of ſtalk which is general to all theſe plants, and is not found in any others.

The terms uſed in deſcribing the ſtalks of plants are, a *ſimple* ſtalk, one which runs up undivided from the root to the top.

Naked ſtalk, one that has no leaves.

Folioſe ſtalk, one with leaves on it.

Ramoſe ſtalk, that which ſends out branches.

Erect ſtalk, that which riſes ſtraight up.

Oblique ſtalk, that which is ſlanting.

Voluble ſtalk, that which twiſts round other things.

Flexuous ſtalk, that which bends.

Reclinate ſtalk, that which ſtoops towards the ground.

Procumbent ſtalk, that which lies on the ground.

Creeping, or *ſarmentous* ſtalk, that which emits roots as it runs along.

If the ſtalk be rounded in ſhape, it is called *round;* if it make two angles, *ancipital;* if three, *trigonal;* if four, *ſquare;* if more, *polygonal.*

If the ſtalk be lightly ridged and furrowed on the ſurface, it is ſaid to be *ſtriated;* if more deeply, *canaliculate;* if full of protuberances, *ſcabrous;* if lightly hairy, *villoſe;* if more roughly, *hiſpid.*

In the *branched* ſtalk, if the branches riſe erect, it is expreſſed by *aſcendant;* if they ſpread, by *diffuſe;* if they are very large, it is called *branchiated.*

If the ſtalk divaricate, or, inſtead of ſending out branches, it divide into them, it is called a *compoſite* ſtalk. If theſe divarications proceed by pairs, or if every branch be divided only into two others, it is called *dichotomous;* if it part into two ſeries of branches, it is expreſſed by the term *diſtichous;* if it part into a multitude of ramifications, it is called *ſubdivided.*

All theſe terms are uſed alſo in expreſſing the different ſtates of the *culm*, which, having no articulations, is called *equal;* when ſcaly, *ſquamoſe.*

STALK, in *Agriculture*, the ſtem or ſtock part of any ſort of grain, graſs, or other kind of plant that is grown as a field crop.

The ſtalks of many ſorts of field plants are much diſpoſed to be affected with different kinds of vegetable diſeaſes, as thoſe of the mildew, the ruſt, and ſeveral other ſorts, which produce ſpeckled, ſpotted, freckled, or other appearances on them.

The ſtalks or ſtems of many different field plants of the cabbage, borecole, rape, and other kinds, are not unfrequently left ſtanding as very uſeful and neceſſary ſpring feed for ewes and lambs, as well as other ſorts of ſheep-ſtock, by the ſprouts or ſmall leaves which they throw out at that ſeaſon in ſuch an abundant manner.

The cutting over the ſtems or ſtalks of ſome ſorts of plants is occaſionally practiſed in the view of increaſing the ſize or quantity of their produce, as in the caſe of the potatoe, and ſome other ſimilarly rooted kinds; but from the trials which have lately been made on the ſubject, it would ſeem that harm rather than good is moſtly the conſequence of the practice.

The ſtalks of graſſes and ſome other plants of that ſort may, in ſome inſtances, and in particular caſes, be cut over, cropped, or fed down by animals, eſpecially of the ſheep kind, with great benefit in rendering them more fine and more ſpreading, by which the herbage as well as the ſward of the land is much improved.

There may likewiſe be other ways in which the management of the ſtalks in different ſorts of plants may probably be beneficial in their cultivation, as by thinning, topping, and ſtripping off their leaves, &c.

STALK, in *Gardening*, the ſtem, upright, or riſing part of any ſort of culinary vegetable or other plant which is raiſed or cultivated in gardens or pleaſure-grounds. The ſtalks of garden vegetables are, for the moſt part, of either the criſp, tender, fleſhy eatable kinds, or of the more hard and ligneous ſorts. The former are, in moſt caſes, rendered more ſuitable and proper as food by being blanched, or having their colouring matters diſcharged from them in ſome way or other, as in celery, endive, ſea-kale, and ſome others. The latter, being commonly only for temporary or future uſe and produce, rarely require any thing to be done to them, except the cutting and clearing away of the irregular or decayed parts towards the cloſe of the ſummer, or other ſeaſon; as they are of the annual, biennial, or perennial kind.

The ſtalks of ſome ſorts of garden plants occaſionally require to be ſtopped in their growth, in order to render them more productive in fruit, ſeed, or other matters, by having their extreme parts twiſted or cut off, as is ſometimes practiſed with the cucumber and other ſimilar plants, as well as in the bean and other crops of that deſcription. And the hard ſolid ſtalks of ſome kinds of garden plants, after they have been cut over, and their heads removed for uſe, are ſtill ſuffered to ſtand in their places, or to be taken up and replanted in other ſituations, in the view of throwing out or ſending forth freſh crops of edible ſhoots of the green kind. See SPROUTS, *Eſculent.*

The ſtalks of all garden vegetables ſhould, in general, be kept in as free and open a ſtate of growth as poſſible, as when too cloſe or too much crowded they never ſucceed ſo well, in whatever intention the plants from which they proceed may be raiſed or cultivated. They likewiſe, in ſome caſes, require to riſe quickly, in order to be good or of a proper quality.

The ſtalks of ſeveral different ſorts, too, ſtand in need of ſupport, as all thoſe of the twining and ſome other kinds.

STALKER, in *Brick-making*. See Brick.

Stalkers, in our *Old Writers*, a kind of fiſhing-nets. Stat. 13 Rich. II. cap. 20.

STALKING, a term of conſiderable import in fowling; applied to a kind of ſcreen, or device to hide the fowler, and amuſe the game, while he gets within ſhot.

Of ſuch devices there are ſeveral kinds.

Stalking-*Horſe*, is a horſe trained up for the purpoſe. This horſe ſhould be choſen of the talleſt and largeſt kind; no matter how old he is, but he muſt be well trained, and ready at command. The horſe, being properly trained, will walk ſlowly along in any ſort of ground, as ſtubble-fields, mooriſh places, or the banks of rivers, and will always feed, or pretend to feed, as he is directed. The ſportſman is to conceal himſelf and his gun behind the horſe's fore-ſhoulder, bending his body low by his ſide, and keeping the whole body of the horſe always full between the fowl and himſelf: when by this means the ſportſman is come ſo near to the birds, that the gun will reach them with ſtrength to kill, he is not to attempt advancing any nearer, that they may not be diſturbed. Some recommend the ſhooting over the horſe's buttocks, and ſome over his neck, but the beſt way is under the neck, and before the breaſt, for by this means the body of the ſportſman is covered by the ſhoulder, and his legs by the legs of the horſe. When the birds are ſhot, the dog will bring them to his maſter, and as they often fall in places where a man cannot come at them, this creature is of very neceſſary ſervice.

This is the beſt of all methods of ſtalking; but as ſuch a horſe is difficult to train, chargeable to keep, and is not always to be had, there are many contrivances introduced to ſupply the place of it: among theſe, the principal are the ſtalking-wheelbarrow, the ſtalking-buſh, and the ſtalking-hedge. The firſt of theſe is to be thus contrived; take a wheelbarrow, made on purpoſe of light fir, and ſet round about it boughs and buſhes in ſuch a manner, that you may ſit in it, and not be diſcovered by the fowl, and drive it along without giving them diſturbance.

The ſtalking-buſh is to be contrived of ſeveral buſhes well platted together, with all their leaves on; it is to be faſtened to a ſtake, which is to have an iron point at the end; the whole is to be the height of a man, and thickly ſet with boughs all the way, from top to bottom. When the ſportſman ſees his game before him, he is to advance ſlowly with this artificial buſh between him and them; when he is come within a proper diſtance, he is to fix the buſh into the ground, by running in the iron ſpike, and then to ſhoot through the boughs.

The ſtalking-hedge is generally made about nine feet long, and a yard and a half high: it is to be made of ſmall wands, ſo woven together, as to give room for the placing of green boughs among them, that it may reſemble a great growing hedge: this is to be carried before the ſportſman, and, in the manner of the buſh, it is to be faſtened down when near enough for the gun to kill from it.

As birds, however, are apt to have ſome apprehenſion of terror from ſeeing a tree or hedge move, theſe machines are to be carried on very ſlowly; and the reſemblance of a real animal, as a horſe, or cow, are better for the purpoſe: theſe may be made of canvas, ſupported on a ſlight frame, and with tails of hair. For pheaſants, woodcocks, and the like fooliſh birds, the common flat figure of a horſe will do; but the water-fowl are generally much more ſhy, and it is neceſſary, for the getting near them, to have the body made hollow, and ſtuffed with hay, or ſome other matter, to keep it out. The proper time to uſe theſe engines is either early in the morning, or late in the evening; for the ſun-ſhine in the middle of the day very ſoon diſcovers to the fowl the imperfection of the engine.

STALL, in *Rural Economy*, a ſort of incloſed place, in which a horſe, cow, or any other kind of animal of the ſame or other deſcription, is fed, foddered, or kept; as a diviſion or ſeparate portion in a ſtable, cattle-ſhed, cow-houſe, or any other building of the ſame nature. See Cattle-*Shed*, Cow-*Houſe*, and Stable.

In the ſtalls, the cattle, in the moſt improved modes, are commonly tied up, and faſtened to upright round poſts of about four inches in diameter, made perfectly ſmooth on their ſurfaces, by means of looſe iron rings and ſmall wooden bows or bands, which are put round the necks of the cattle, and ſlide readily up and down in the rings on the poſts, as the cattle may want them. The upper parts of the bows, yokes, or bands, are moſtly flat, and have two holes in them; and the bow or band parts, which are in general formed of tough ſplit aſh, have a ſort of button or knob at each end of them, which is put into the circular holes of the flat head-pieces, when, by the ſpring of the bows or bands, the knobs or buttons are prevented from returning, by their ſlipping over into nicks or notches made in one end of the head-pieces, where they become fixed until the animal be wanted to be let out, which is readily done by a little preſſure being made on the bow parts. Theſe ſtalls have, in many caſes, cribs alſo contrived for the cattle to eat their fodder out of or in. And paſſages are not unfrequently formed in front, or before the heads of the cattle, for the convenience and facility of giving them their fodder from, as much ſaving in time and labour is thereby produced.

The ſtalls in the cow-ſheds, houſes, or *linneys*, as they are called in ſome of the ſouth-weſtern diſtricts of the kingdom, have their boxes or cribs ſo formed, as to contain the hay, ſtraw, and other ſimilar matters for the cows in winter, and the lucern, tares, vetches, and other ſuch materials, in the ſummer ſeaſon. They have alſo troughs for turnips, potatoes, cabbages, and other food of the ſame kind. And likewiſe vealing places for the calves, which are rendered a little dark, in order to promote the proceſs of fattening them. There are ſometimes, too, large ſeparate ſtalls or diviſions for ſuch cows as are near calving, or have juſt calved. For young cattle-ſtock they are occaſionally divided, alſo for three-years old, two-years old, and one-year old ones, in order that the young beaſts may not get injured or inconvenienced by running among the others. And the head-ways, by being made ſhorter in proportion to the ſize of the different year's growth of the animals, render them capable of all dunging into the ſame grip or gutter, and conſequently of being more readily cleaned and kept in order.

The diviſions or ſtalls for the fattening of bullocks or oxen ſhould always have ſufficient ſpace, without allowing any unneceſſary waſte of it, as where two oxen are fattened in one ſtall from eight to ten feet, that is, four or five feet to each beaſt, according to the ſize of the beaſt uſually fattened. Theſe diviſions, in the beds or foundations of them, ſhould conſtantly decline in a gentle manner backwards, ſo as to draw off the urine, and have a ſmall riſing at the heels of the animals, as in the cow-ſheds or houſes, and for the ſame purpoſes.

There ſhould be a crib or manger in each ſtall, which ſhould have the conveniency of a ſeparate partition for different articles of food, as meal, oil-cake, bran, chaff, and others of the ſame kind, without their mixing or being blended with turnips, cabbages, potatoes, hay, or other ſuch matters of fodder; and beſides, a pump for ſupplying water to the animals, conducting or leading it to the different troughs which are formed for receiving it in each of the ſtalls.

In ſome caſes, keelers are put in every ſtall for affording water to the cattle, which have troughs of communication, in order to convey it from pumps in the farm-yards to large general troughs on the outſide of the ox-houſes, which is afterwards ſeparately conducted to each keeler, ſo that all the time and trouble in untying, tying, and driving to the water, are ingeniouſly and uſefully avoided. The keelers or troughs, in theſe circumſtances, are placed even with the cribs or mangers, and are moſtly of the ſame ſizes and dimenſions.

In connection with all large ranges of ox-ſtalls, there ſhould always be a weighing machine, in order that the owners may at any time inſtantly aſcertain what are the ſtate and progreſs of the beaſts, as well as that the improvement they make, and the expence of food, or the fleſh, and the food neceſſary to produce it, may be fairly compared. By this means, the ſorts of cattle which give the greateſt quantity of fleſh meat with the ſmalleſt quantity of food, in theſe feeding ſtalls, may likewiſe be uſefully and readily decided, which is a point of the utmoſt importance to the ſtock-feeding farmer.

Stall-*Fed*, a term applied to animals fed in the ſtall with dry food, and not with graſs or other ſimilar matters.

This ſort of feeding is highly beneficial to the farmer, in raiſing and producing large quantities of the beſt kind of dung manure; but is rather expenſive in the materials, and the different conveniencies which are neceſſary for the practice of it. See the following article.

Stall-*Feeding*, the art or proceſs of fattening neat cattle in the ſtall. The beſt practice in this ſort of fattening is, probably, that of wholly confining them to the ſtalls, which is uſually termed ſtall-feeding; as by this means they are kept quiet, and free from interruption, and of courſe feed more quickly, and with greater regularity, which ſeem to be points of great importance in this ſyſtem of management with theſe animals; though there are ſome who are ſtill in favour of the yard management.

In regard to the ſorts of food that may be employed in the way of winter fattening the animals in this practice, the principal of the more ſucculent kinds are carrots, parſnips, potatoes, Swediſh turnips, cabbages, common turnips, grains, and ſome others; and of the more dry ſorts, oil-cake, and other matters of that kind, oats, barley-meal, rye-flour, bean and pea-meal, and others of the ſame nature, with different ſorts of ſtraw and haulm cut into chaff by means of machinery, or hay cut in the ſame manner. It is uſual with ſome to employ the different meals in a ſtate of mixture in nearly equal proportions, except the bean-meal, which, from its heating quality, is moſtly made uſe of in ſmaller quantities. But on the principle of freſh ſorts of food having a more powerful effect on the ſyſtems of animals, when firſt applied, it may be more beneficial to have them given in alternation, or at diſtant intervals, as their effects may in this way be more fully experienced. And in reſpect to the cut ſtraw and hay that are made uſe of in this way, the firſt ſhould, contrary to the practice uſually adopted, be prepared from that which is freſh threſhed out, and not ſuch as has been long packed together, and is become fuſty. The hay, inſtead of being of the inferior kind, ſhould be the beſt the farm affords, and ſuch as is not in the leaſt injured in the ſmell or taſte by keeping. It has, however, been ſtated by Mr. Dark of Herefordſhire, an experienced grazing farmer, that the more inferior ſort of hay has, by the addition of a very ſmall proportion of common ſalt, been made to be preferred to the beſt, when not prepared in that way. The quantity of it uſed with flooded meadow hay was only about eight pounds to the ton; and his oxen of the breed of that diſtrict did better with it than others which had the beſt hay. The whole of the advantage is aſcribed to the portion of ſaline matter mixed with it, acting as a ſtimulus or condiment on the ſtomachs of the animalss.

Upon the principles of this ſort of feeding, the author of the Syſtem of Practical Agriculture has offered ſeveral phyſiological obſervations, that deſerve attention, but which our limits will not allow us to inſert.

In this management, it is a matter of the utmoſt importance for the animals to be kept conſtantly free from ſtanding in any dirt or naſtineſs, by having the dung daily removed and cleaned out, and their ſtandings ſwept out as clean as poſſible; being then littered down with dry clean litter, ſo as to prevent any ſort of naſtineſs from adhering to their ſkins, or affording them uneaſineſs during their fattening. And in order to effect the littering in the moſt perfect manner, as much ſtraw, or other ſimilar matters, ſhould be made uſe of as can be converted into manure, as from one to two or three tons each beaſt; as the dung will fully repay the expence of it, in the improvement which it muſt afford to the land on which it is applied. In this proceſs it is alſo of much advantage to have the cattle ſheltered, and kept in a due degree of warmth, without being too hot; as when the heat is too great, there may be diſadvantage by too much perſpiration being produced. In regard to the giving of the food in this proceſs, the ſtate of the appetites of the cattle, or other animals, ſhould be nicely watched, and the quantities adapted, ſo as that it may be eaten up perfectly clean. With the more ſweet ſucculent ſorts, too much ſhould not, however, be given at a time; but be duly combined with ſome of the dry kind. And where cut dry meat is chiefly employed, it is the beſt practice, probably, to keep ſome of it always in the cribs or boxes, ſo that the cattle may take it at pleaſure, or as they find themſelves diſpoſed.

It has been ſtated, that where ſucculent food is made uſe of with cut dry meat, which is in general a more profitable method to the farmer than that of having recourſe to corn and oil-cake, or the different ſorts of meals ſtated above, carrots, parſnips, potatoes, and the Swediſh turnip, would ſeem to ſtand the higheſt as articles for this uſe; the common turnip and cabbages having been found much inferior in their fattening properties. The two firſt are equal to almoſt any other ſort of food in this view, being capable of fattening the largeſt cattle. And the moſt general practice is to employ theſe roots and plants without any other preparation, except that of being ſometimes cut, ſliced, or chopped, in a box for the purpoſe; giving only a ſmall proportion at a time, at three or four different periods in the courſe of the day, in cribs properly contrived for the purpoſe; due ſupplies of ſuch cut ſtraw, in mixture with hay, being, where neceſſary, provided and given in the intervals of ſuch feeds. It is found that in this method much leſs water will be neceſſary, than when dry meat is wholly made uſe of in the proceſs, as the animals are much leſs thirſty from the ſucculence of the food.

Farther, the nutritious properties of the carrot have been found very conſiderable, when employed in this way; and this root has ſome great advantages, as the animals readily take to it, and a great proportion of food is capable of being raiſed on the acre. It was found by Mr. Young, in his trials with this root, that the conſumption with an ox of about ſixty ſtone weight was *per* day about ten ſtone, giving in addition cut hay and chaff, or ſome other ſimilar dry material. The parſnip is alſo a root of equal, if not ſuperior, merit in this management. An acre of either of theſe roots would complete the fattening of two ſuch beaſts as the above, if taken from the paſtures in a half-fattened condition. It has indeed been ſuggeſted, that theſe two roots and the potatoe approach the neareſt of any to that of the oil-cake in their fattening properties, but are certainly inferior to that ſubſtance in this intention.

The white and red beets, and the ſcarcity root, or mangel wurzel, have alſo been found highly beneficial in this application.

And there have been many trials made with potatoes in the ſtall-fattening of animals, in which it has been fully ſhewn that, both in the raw and boiled or ſteamed ſtates, they are a root that occaſionally anſwer very well. It has been found, that ſmall cattle of the Welſh and Scotch runt kind have been aſcertained to conſume about a buſhel each in the courſe of the day, with from fourteen to ſixteen pounds of hay, or ſome other cut dry food. In the raw ſtate, ſome dry food of theſe ſorts is indiſpenſibly neceſſary, in order to correct the purgative quality of the root; and when boiled or ſteamed, it has likewiſe a good effect in affording due diſtention to the ſtomach. When given to milch-cows in a raw ſtate, the milk is found to be greatly increaſed, but to be of a poor thin quality. There can be no doubt, but that where the ſteaming or baking of the root can be accompliſhed at a cheap rate, and in a convenient manner, the food will be much better ſuited to the purpoſes of ſtall-feeding, as being much more nutrient and agreeable to the animals.

On this ſubject it is ſtated by an excellent grazier, J. H. Campell, eſq. of Charlton, in Kent, in anſwer to queries propoſed to him by Mr. Young, that 100 buſhels of potatoes and 700 weight of hay are generally ſufficient to fatten an ox that thrives tolerably well. And in giving the roots, they ſhould at firſt be uſed in ſmall quantities, which ſhould then be gradually increaſed to one or two buſhels *per* day, dry food being always intermixed, and the proportion of hay being uniformly regulated by the effect which the potatoes produce on the bowels. There ought to be at leaſt four or five ſervings in the courſe of a day, as according to the quantity of roots which a beaſt can be induced to eat with appetite, he will fatten the ſooner, and of courſe with leſs expence to the farmer, and conſequently more profit be obtained. The hay ſhould be cut once, or, if it be not very weighty, twice along and three times acroſs the truſs, ſo as to be in ſquare pieces of eight or ten inches in proportion; in which ſtate the cattle will eat it and digeſt it more readily, while their fattening is conſiderably expedited. But the potatoes need not, he thinks, be cut, except at firſt, in order to entice the beaſt to eat them; but they ought always to be freſh and clean. Corn or meal is not abſolutely neceſſary; but when at a moderate price, it may be employed with advantage. But in caſe a ſcowering ſhould be brought on by the uſe of raw potatoes, which often happens, the quantity of hay, meal, or other dry food given with them, ſhould be increaſed conſiderably, till the beaſts become accuſtomed to the roots, when this inconvenience will be removed.

Stall-feeding of bullocks with potatoes, given in different ſtates of preparation, has been for ſome time extenſively practiſed in Suſſex, and is much approved of by many. They there find that a beaſt of from one hundred and forty to one hundred and ſixty ſtone weight eats from one to two buſhels of the roots in the courſe of the day, but conſumes little hay, as not much more than ten or twelve pounds, in that ſpace of time. This root has probably not yet been tried, by giving it when artificially ſprouted; but it would perhaps anſwer well in this way. Some have, however, lately begun to queſtion the merit of potatoes in this mode of cattle-feeding, as not being ſo valuable, when compared with ſome other ſorts of food. And a careful experimenter, who was largely in the practice of fattening oxen with them, it is ſaid, gave them up, from the conviction that, with every advantage of breed, attention, warmth, and cleanlineſs, in regard to the animals, they would not pay more than four-pence the buſhel.

Further, the Swediſh turnip, when it is cultivated in a proper manner, is a moſt valuable root, when uſed in this intention, being very ſweet and palatable to the animals, and at the ſame time poſſeſſing more nouriſhing power than the common turnip; of courſe, going much farther. In ſome trials which we have lately attended to, it was found to have the advantage nearly in the proportion of one-fourth; and in other experiments, it is ſaid to have gone ſtill farther in this uſe.

Alſo cabbages, in combination with dry chaffy materials of different kinds, have been long known to anſwer well in keeping ſtore animals in the winter; and, when made uſe of with good hay, to be capable of fattening large cattle in an expeditious manner. It has been found by correct trials, that the daily conſumption of this vegetable is moſtly in the proportion nearly of one-fifth the weight of the animal: of courſe, an ox weighing about ſixty ſtone conſumes about twelve ſtone *per* day. In ſome experiments made long ago by Mr. Turner, detailed in the ſecond volume of Mr. Young's Six Months' Tour, an ox of eighty ſtone was found to conſume fifteen ſtone of this plant, with the addition of half a ſtone of hay. And that with regard to its properties of feeding oxen put to it, when in low condition, in November, they became in a ſtate of fatneſs, and ready for the market, in the March following, having the weight of eighty ſtone; moſtly increaſing in value in the courſe of four months, about five pounds ten ſhillings. It is evident that, in this proportion, an acre of this crop of thirty tons would be ſufficient for ſtall-fattening three beaſts of the ſame ſize and weight.

And common turnips, according to Mr. Marſhall, are, in Norfolk, given in different ways to cattle in fattening them; as by being drawn and thrown thinly and evenly upon the graſs, ſtubble, and other lands, in order that the cattle may conſume them in ſuch ſituations; in which caſes, they have not any allowance of hay during the whole proceſs of fattening.

But another mode of giving this root to fattening cattle is, it is ſaid, by means of cloſe bins, or ſmall cribs, with boards or bars nearly cloſe at the bottom, while the beaſts are kept in a looſe ſtraw-yard. Theſe bins are diſperſed over the yard, and the turnips are put into them whole; the tap-root, and alſo the tops, unleſs they are freſh and palatable, being previouſly cut off, ſo that the fattening animals receive only the bulbs; the tops, if eatable, being conſumed by ſtore cattle. And that while the bullocks are in the yard, they have the ſtraw ſometimes given them in cribs, and at others it is ſcattered in ſmall heaps about the yard, twice or thrice a day: the quantity thus eaten is very trifling; and with the laſt mentioned management, the yard becomes evenly littered without farther trouble. But this mode of fattening is attended with ſomewhat more labour than that of throwing turnips abroad, which, it is thought, is the preferable management, if the ſoil be ſufficiently dry to ſupport the ſtock, and light enough to ſtand in need of being rendered firm by treading: on the contrary, where the land is deep, and the ſeaſon is wet or ſevere, the ſtraw-yard is the more comfortable place, provided it be kept dry and well littered, and be furniſhed with open ſheds, in which the ſtock can ſhelter themſelves. For though the *teathe* of fattening cattle abroad is greatly beneficial to light ſoils; yet, if bullocks, while fed in the yard with turnips, are well littered, they will make a large quantity of excellent manure, that will amply compenſate for the additional labour occaſioned in that way.

A ſtill farther method conſiſts in keeping the cattle tied up in ſtalls, hovels, or beneath open ſheds, with mangers or troughs for receiving the turnips, which, in this caſe, are frequently ſliced, or more generally, though perhaps leſs eligibly, cut into quarters, by means of a ſmall chopper, upon a narrow board or ſtool, beneath which is a baſket for catching the pieces.

It has, however, been ſuppoſed that turnips, though very frequently employed in the proceſs of ſtall-feeding, are greatly inferior to cabbages, as, beſides their being more liable to injury, they probably poſſeſs the fattening property in a leſs degree than any of the ſubſtances that have been noticed above. And the proportion in which they are conſumed by the fattening ſtock has been found to be ſomething more than a third of the weight of the cattle, by ſome; but by others, about a third in the day, as ſtated in the Gentleman Farmer. However, in other experiments, carefully made, an ox of from ſeventy to eighty ſtone has been aſcertained to eat ſomething leſs than three hundred weight in the courſe of the day, beſides chaff and hay; and ſmall cows of about thirty ſtone, one hundred weight and three quarters in the ſame ſpace of time. And in the Rev. Mr. Cloſe's trials, it was found, that when conſumed in ſtalls or ſheds, an acre of good turnips will completely winter-fat an ox of fifty ſcore, beſides affording manure for an acre and a half of land; but if fed upon the land, two acres will not fatten one ſo well, and the dreſſing will be partial, and of but little value. When this root is given in the ſtall, from its very ſucculent nature, it becomes neceſſary to employ as much dry food as poſſible during the uſe of it, in order to the expeditious fattening of cattle by ſuch means.

It has alſo been practically remarked by a late writer, that the turnip is often employed in the fattening of ſheep, ſomewhat in this way; and that in this application it is frequently advantageous, where the management is conducted with judgment. But to derive the greateſt profit from this practice, it is probably the beſt method to only make uſe of them for ſuch ſheep as are in a conſiderable ſtate of forwardneſs; as ſuch as are poor, when turned to this ſort of food, are ſeldom found to pay well for it. Every farmer who has applied turnip crops in this way, muſt, it is ſaid, have found this to be the caſe. Where the ſoils are ſufficiently dry, the beſt method of conſuming them may be on the lands, by means of hurdling; but under the contrary circumſtances, they may be drawn and eaten upon a dry piece of ſward.

Turnips, as well as potatoes, have been ſteamed for this purpoſe. See STEAMING *of Cattle-Food.*

As to the uſe of brewers' grains, they can only be had recourſe to in this way in particular ſituations, as near large towns, or other places where they can be had at a reaſonable rate, and in ſufficient quantity: and of this ſort of food, that which is the produce of large diſtilleries is found the moſt beneficial in this ſort of feeding. The quantity made uſe of for moderate ſized beaſts is uſually from a buſhel to a buſhel and a half, three times in the courſe of the day; hay or cut dry food being given between the periods of feeding with theſe matters. But this ſort of ſubſtance ſeems to be much leſs powerful in its fattening properties, than any of thoſe articles that have been mentioned above. Still, with good hay, it is probable that theſe matters may be made to fatten animals in a tolerably expeditious manner.

But beſides theſe different ſubſtances, there are others of a leſs ſucculent quality employed in this practice: the firſt, perhaps, in reſpect to the properties of feedng, is that of *oil-cake*, that is, the refuſe material left after expreſſing the oil from linſeed. See OIL-*Cake.*

It is aſſerted that theſe cakes have a very extraordinary effect on cows before calving, cauſing their milk to flow more copiouſly, and preparing the animal in a good manner for the period of calving. But as the fat of beaſts, fattened on oil-cake, is not ſuppoſed by ſome ſo good for food, and to be of a leſs firm texture, it has been adviſed to ſubſtitute linſeed jelly, which is infinitely ſuperior, and which, when mixed with a due proportion of hay or meal, affords an excellent compoſition for ſtall-feeding and fattening. This jelly is prepared in the following manner: to ſeven parts of water one part of linſeed is only put, for 48 hours; then boil it ſlowly for two hours, gently ſtirring the whole, leſt it ſhould burn; afterwards it ſhould be cooled, and mixed with meal, bran, or cut chaff. In the experiment of Mr. Moody, an eminent grazier, two quarts of this jelly were uſed *per* day to every large bullock, which proportion amounts to little more than one quart of ſeed in four days, and produced a great ſaving in the article of food in this proceſs. And in America, experiments have been made with *linſeed-oil*, mixed with the meal of Indian corn. The ſtall-fed ſteer, to which this compoſition was given, was obſerved to thrive rapidly, and to ſweat moſt profuſely; but, through inattention, too large a proportion of oil was given at one time with the food, which diſguſted the beaſt, and occaſioned the experiment to be diſcontinued. There can, however, be no doubt but that linſeed or flax-feed jelly is more agreeable to cattle than cake, while it renders them leſs liable to ſurfeit, in caſe an extra quantity ſhould be accidentally given; and is leſs liable to affect the meat with a peculiar taſte than either oil or cake, and conſequently it merits a further trial. To each bullock, or fattening animal, about half a gallon of jelly may be given every day, mixed with meal and cut ſtraw; but it will be requiſite to change this food about a month before the beaſt is killed, to prevent, if poſſible, the fleſh from retaining the flavour of the oil-cake or jelly, as they, each of them, may be liable to affect it in ſome meaſure.

Further, where ſheep are fattened with oil-cake, they require it to be brought into a much finer ſtate than for cattle in general, and which may then be mixed with bran, or other ſimilar ſubſtances, and put in the troughs or cribs for the animals to feed at.

Alſo, on the ſame principle as that of oil-cake, the uſe of linſeed-oil and bran has been attempted, but probably with leſs ſucceſs in the application. The conſumption in this mode, for beaſts of the ſmaller ſize, is ſomething more than half a peck of bran three times in the day, with a third of a pint of linſeed-oil well ſtirred into it: with this, good hay or cut chaff is uſually given. But it is a mode attended with more trouble than that of cake-feeding, without any great ſuperiority in the effect that is produced; and it can only be employed where the oil is cheap, and to be had with convenience.

Linſeed and barley mixed and ground together, in the proportion of two pecks of the former to two buſhels and a half of the latter, have been found very beneficial in ſtall-feeding, in Suſſex, when given to ſummer-ſoiled or paſtured animals in the yards, in the beginning of the winter ſeaſon. Of this mixture each ox has two buſhels in the week given him, beſides wheat-chaff and hay. They fatten rapidly, it is ſaid, in this way.

And another article, equal, if not ſuperior, to any of theſe laſt kinds, in this ſort of fattening, is that of oats, which may be given either in the ſtraw or when threſhed: for neat cattle it is probably beſt given in the former ſtate, but for ſheep in the latter, in ſhallow troughs or cribs made for the purpoſe, ſo as to prevent its being blown out of them. The conſumption, in this ſort of food by ſheep, is uſually from two or three to four or more pounds each *per* day, according to the ſize and kind which are fattened; but with neat cattle it muſt be proportioned to the animals in different reſpects.

Where barley or other meals are employed, they are beſt made uſe of in their dry ſtates for ſheep, in mixture with the cut or other matters that are given at the ſame time in their cribs or bins; but for neat cattle they are ſometimes mixed up and blended with liquid materials in different forms. Theſe ſubſtances have much effect in promoting the fattening of the animals; but they can ſeldom be made uſe of with much profit, except for the beſt ſort of cattle or ſheep. Where ſheep are fattening on the turnips, theſe ſorts of food are alſo excellent in correcting the watery properties of that root. Several other ſubſtances of the dry kind have likewiſe been employed in the ſtall-feeding of different ſorts of animals, ſuch as the duſt and combs of malt, cut pea and bean-haulm, and other ſimilar matters, which have been found highly beneficial.

Alſo, in this practice, the uſe of food in a ſour ſtate has been adviſed by ſome; as in this condition, it is ſaid, experience has ſhewn it to be uſeful in the keeping and fattening of ſwine. But experiments are ſtill wanting on this ſubject. And on the ſame principle, it has been recommended as a food for large cattle, which has been done by fermenting rye, flour, and water, into a kind of paſte, and then diluting it with water; and alſo, when thickened with hay, cut ſmall, it is ſaid to fatten quickly. This practice chiefly prevails in France, whence it was introduced into this country. But concerning the efficacy of acid food in ſtall-fattening animals, there is much difference of opinion.

It may be ſtated, that it is now found that the waſh or refuſe of malt, remaining after diſtillation, which was formerly applied excluſively to the feeding of ſwine, may be uſed in this way with profit; and that it has, of late years, been applied with much ſucceſs. The cattle fed in this manner are aſſerted, not only to repay the expence of their keeping, by fattening ſpeedily, but alſo to yield a large quantity of valuable manure. This ſubſtance has been extenſively and ſucceſsfully applied in ſtall-feeding by Meſſrs. Hodgſon and Co., the proprietors of Bolingbroke-Houſe diſtillery, Batterſea, near London, where the proprietors have erected ſtalls for fattening about 350 head of cattle at one time, with waſh and grains, and a certain portion of hay *per diem*, with the view of enabling them to chew the cud. They are ſaid, between October and April, which is their regular working ſeaſon in the diſtillery, to fatten about 600 bullocks; having generally about 300 in the houſe tied up at one time, and about 100 in an adjoining orchard to take in, to replace ſuch as are ſold off, or in conſequence of any expectation of an approaching advance in meat. They have no ſtated period for fattening theſe bullocks, being regulated entirely by the ſtate of the markets; but from ten to ſixteen weeks are about the uſual time, and the cattle are found to gain, upon an average, from three to four ſtone *per* week.

Another ſubſtance has been employed in this way with equal ſucceſs, which is that of moloſſes or treacle; though the expence incurred by the uſe of this article will probably prevent its general application. It was firſt uſed in the Weſt Indies by Mr. Millington, who found it, in combination with farinaceous ſubſtances, and, when theſe could not be procured, with cane-tops, oil-cake, and other articles of dry food, together with a little hay, or not too green fodder, greatly to expedite the fattening of cattle in general, and of old and decayed oxen in particular. He gave from half a pint to a pint of moloſſes twice in the day to very ſtarving animals, which had been exhauſted by continual and ſevere labour for a ſeries of years. In adopting this article, a gallon of oats, or other damaged grain, roughly ground, or the ſame quantity of potatoes, ſhould be boiled in a ſufficient proportion of water to form a thick waſh. It muſt be well ſtirred while on the fire, to prevent it from burning or ſticking to the ſides of the veſſel; and when it becomes cool, the mixture is to be formed into balls of about one pound weight each. Theſe balls are divided into two equal portions, which, being previouſly immerſed in the treacle, are given to the beaſts morning and evening. They will devour them with eagerneſs, and will ſpeedily thrive and fatten by the addition of a little hay, or any green fodder, that is not too ſucculent. Farther, one or two ſpoonfuls of ſalt may be diſſolved in the compoſition, which will contribute to preſerve the health of the animals; and in caſe corn cannot be conveniently procured and ground, pulverized oil-cake, diluted in water, and ſeaſoned with a ſmall quantity of ſalt, with the ſame proportion of moloſſes, may be advantageouſly ſubſtituted. And there are probably many other refuſe ſaccharine or ſweet ſubſtances, formed in different manufactures, that might be employed in the fattening of cattle in this way.

Where this ſort of buſineſs is conducted on an extenſive ſcale, it is of the greateſt utility to have a machine for the occaſional weighing of the cattle, as they advance in their fattening; as, without ſuch aſſiſtance, there are but few perſons who are capable of judging whether they go on in a profitable manner or not. But by weighing them from time to time, at the diſtance of every eight or ten days, in the morning before they are fed, this may be correctly aſcertained; and where they fall off, or do not advance in a ſufficient degree to the preceding weighing, ſuch changes may be made in their food, water, and management, as are the moſt likely to promote their fattening in the moſt perfect manner, and with the greateſt profit.

STALLAGE, Stallagium, in our *Old Writers*, the liberty, or right of pitching and erecting ſtalls in fairs and markets, or the money paid for the ſame.

STALLATI, in *Geography*, a town of Naples, in Calabria Ultra; 1 mile E.S.E. of Squillace.

STALLED, in *Rural Economy*, a term ſignifying tired with eating in animals, or a kind of loathing of food in them. It alſo ſignifies ſet faſt in a ſlough or bad road with carts or waggons.

STALLING, in *Agriculture*, a term applied to the practice of foddering, feeding, and fattening neat cattle in ſtalls, or the tying or binding them up in them for any other purpoſe.

STALLION, in the *Manege*, in French *etalon*, a ſtone-horſe kept to breed. See Horse, and *Breeding of* Horses.

In the reign of Henry VII. a large number of mares, as well as geldings, were turned after harveſt into the common paſtures, and no ſtoned horſes were allowed to mix with them; and it is at this day contrary to law to turn a ſtoned horſe into a common paſture. Thoſe horſes which were kept to cover mares were always confined in ſafe and incloſed grounds, but more frequently in the ſtable, and were called "equi ad ſtabulum," by contraction, *ſtallum*. Hence were derived the Italian term "ſtalloni," the French "etalon," the Engliſh "ſtallion," or "ſtalled" horſe; which expreſſion prevails, and is in uſe at preſent with regard to the ox, which ſometimes being kept from the paſture in order to be fattened, is called "the ſtall-fed" and "ſtalled" ox. In the reign of the ſucceeding prince, particular regard was paid to the raiſing of a breed of good and ſtrong horſes, and laws were made for the more certain attainment of this end. The only method of ſecuring ſtrength and ſize in the progeny, is to ſelect the ſires and dams of a certain proportion, ſize, and mould, and to permit no mare or ſtallion to breed, but under theſe reſtrictions. In order further to ſecure a breed of large horſes, a ſingular kind of law was paſſed, which obliged every archbiſhop and duke, under penalties, to keep ſeven trotting ſtoned horſes for the ſaddle, each of which was to be fourteen hands high at the age of three years. Afterwards minute directions were iſſued, with regard to the number of horſes of the ſame kind, which were to be kept by other ranks and degrees, each in proportion to their circumſtances and ſtation.

The reaſons for enjoining ſtone-horſes to be kept muſt have been for the ſake of breeding, and for the ſuperior labour they were thought to be able to undergo; and as they were more expenſive to maintain than mares or geldings, it being neceſſary to ſeparate and keep them apart, the rich and noble only were required to keep them in numbers proportioned to their rank and ability; while the lower people uſed geldings, for the advantage of turning them to graſs. Brood-mares, two at leaſt, were ordered to be kept by thoſe who had parks, incloſures, and other conveniencies. Berenger's Horſemanſhip, vol. i.

STALLUPONEN, or Stallupehonen, in *Geography*, a town of Pruſſian Lithuania, the principal trade of which conſiſts in cattle; 33 miles S.E. of Tilſit. N. lat. 54° 33′. E. long. 22° 58′.

STALOWITZ, a town of Lithuania; 10 miles from Pinſk.

STALTWASSER, a river of Wurtemburg, which runs into the Lein, 2 miles S. of Welzen.

STAMBACH, a town of Germany, in the principality of Culmbach; 12 miles E. of Culmbach.

STAMEN, in *Botany* and *Vegetable Phyſiology*, the ancient Latin name for the part in queſtion, now become Engliſh in the place of its old appellation, *chive*. The ſtamens are organs of impregnation, eſſential to every flower, either in the ſame individual with the piſtils, or in a correſponding one of the ſame ſpecies. (See Pistillum, and Fecundation *of Plants*.) They are ſeated externally with reſpect to the piſtil, internally with reſpect to the calyx and corolla. They are inſerted either into the calyx, the corolla, or the receptacle, rarely either upon the germen, or the ſtyle. Their number differs in different genera or ſpecies of flowers, from one to an hundred or more.

Each *Stamen* commonly conſiſts of two parts, the Filament and Anther; ſee thoſe articles. The latter only is eſſential, being of a capſular texture, containing the Pollen, whoſe nature and office will be found explained in its proper place. The *Anther*, when arrived at maturity, either burſts by the contraction of its membranous coat, or opens by appropriate cells for the diſcharge of the pollen, of which laſt circumſtance the genus *Erica* affords beautiful examples. In *Laurus* and *Leontice*, even in ſome ſpecies of *Solanum*, each cell of the anther has a proper lid. Theſe cells are uſually two; but in *Tetratheca* and *Vatica* they are four. Sometimes the anther is ornamented with a creſt, or with a pair of briſtles, of both which various *Ericæ* exhibit ſpecimens. In *Pinus* the creſts of the anthers prove uſeful for ſpecific diſcrimination.

The *Stamens*, according to their number, ſituation, and proportion, furniſh the leading principles of diſtinction in the artificial, or ſexual, ſyſtem of Linnæus; ſee Classification.—Theſe organs are liable to be changed into petals, in what are termed double flowers; and if that change be complete, they can no longer ſerve the purpoſe of impregnation.

STAMFORD, in *Geography*. See Stanford.

Stamford, a townſhip of Upper Canada, in the county of Lincoln, lying on the W. ſide of Niagara river, and S. of Newark. A port of entry and clearance is eſtabliſhed in this townſhip, on the N. bank of Chippawa river, near the bridge.—Alſo, a townſhip of Vermont, in Bennington county; containing 378 inhabitants.—Alſo, a poſt-town of Connecticut, in Fairfield county, on a ſmall ſtream called Mill-river, which diſcharges itſelf into Long Iſland ſound; containing a congregational and epiſcopal church, and 4440 inhabitants; 10 miles S.W. of Norwalk, and 44 N.E. of New York. This townſhip was formerly called "Rippowanns," and was ſettled in 1641.—Alſo, a poſt-town of New York, in Delaware county, taken from Woodſtock, and incorporated in 1792, containing 284 families, and 1658 inhabitants; 60 miles S.W. from Albany.—Alſo, a poſt-town in Lincoln county, Kentucky; 628 miles from Waſhington.

Stamford *Iſlands*, a cluſter of ſmall iſlands near the coaſt of North Carolina. N. lat. 34° 37′. W. long. 77° 10′.

STAMINA. See Stamen.

Stamina, in the *Animal Body*, are thoſe ſimple, original parts, which exiſted firſt in the embryo, or even in the ſeed; and by whoſe diſtinction, augmentation, and accretion by additional juices, the human body, at its utmoſt bulk, is ſuppoſed to be formed.

All that is eſſential to the animal, are the ſtamina, which exiſt *in ovo*; the reſt being foreign, additional, and even accidental.

The ſtamina ſeem to coincide with the ſolids, which are ſurpriſingly ſmall in quantity.

STAMITZ, John, in *Biography*, the illuſtrious father of a renowned muſical family, concert-maſter and director of the chamber muſic, or court concerts of the elector palatine at Manheim, in 1756, was born at Teutechebrodt, in Bohemia, where his father was cantor in the principal church. It was during his time, and by his example, that German ſymphonies, in a ſtyle different from the overtures of Lulli, Handel, and the Italian opera compoſers, began to be cultivated and in favour all over Europe. It was under him that the late earl of Kelly placed himſelf as a ſcholar on the violin, and a ſtudent in compoſition; and it was alſo under him that the Manheim band, by its experiments and new effects, became, during thirty years, the moſt celebrated in the muſical world.

The genius of Stamitz was truly original, bold, and nervous: invention, fire, and contraſt, in his quick movements; a tender, graceful, and inſinuating melody, in the ſlow; together with the ingenuity and richneſs of the accompaniments; characterize his productions, all replete with great effects, produced by an enthuſiaſm of genius, refined, but not repreſſed, by cultivation.

The following is a liſt of his principal works, which we adviſe true lovers and judges of good muſic to purchaſe wherever they can find them: as, though more than forty years old, in ſpite of faſhion and a rage for novelty, they will long continue to be good muſic; "VI Sonate da Camera à 2 Violini e Baſſo," Noremb. 1761. "VI Sonate à Violino Solo e Baſſo, Op. 6," Paris. "VI Concerte de Violon à pluſieurs Inſtrum." Par. "VI Sonates choiſies pour le Clavecin avec Violon, Op. 1ma." Paris. In MS. he left unpubliſhed, ſix ſymphonies, twenty-one violin concertos, two harpſichord concertos, and nine violin ſolos.

Stamitz, Charles, the worthy ſon of ſo great a father, was born at Manheim in 1746, and ſtudied under Canabich. In 1767 he was admitted into the elector palatine's chapel, as principal ſecond violin. He has travelled ſince all over Europe, and given ſpecimens of his ſpirited compoſitions and performance, particularly on the tenor. He was in England about the year 1780, and performed at Bach and Abel's concerts. He compoſed a duet for a violin and tenor, which Cramer and himſelf performed to the wonder and delight of all hearers. This duet has often been played ſince by great performers on the tenor, violin, and violoncello. On this inſtrument, we believe Linley was the laſt.

In 1770 Charles Stamitz went to Paris, where he gained great applauſe by his compoſitions and performance on the tenor and viol d'amour. In 1785 he returned to his own country, and exerciſed his ſkill and talents at Berlin, Dreſden, and Heſſe Caſſel: in all which places he continued writing for almoſt all kinds of inſtruments.

Stamitz, Anthony, the younger brother of Charles, was born in 1753, and became eminent likewiſe by his compoſitions and performance.

STAMMERING, in *Phyſiology*, an heſitation or interruption of ſpeech, which ſeems generally to ariſe from fear, eagerneſs, or ſome violent paſſion, that prevents a child's articulating rightly, by the confuſion which it occaſions in the vibrations that deſcend into the muſcular ſyſtem, ſo that, finding himſelf wrong, he attempts again and again, till he hits upon the true ſound. It does not therefore begin, in general, till children are of an age to diſtinguiſh right from wrong in reſpect of pronunciation, and to articulate with tolerable propriety. A nervous diſorder of the muſcles of ſpeech may have a like effect. When the trick of ſtammering has once begun to take place in a few words, it will extend itſelf to more and more from very ſlight reſemblances, and particularly to all the firſt words of ſentences, becauſe then the organs paſs in an inſtant from inactivity to action, whereas the ſubſequent parts of words and ſentences may follow the foregoing from aſſociation; juſt as in repeating *memoriter*, one is moſt apt to heſitate at the firſt word in each ſentence. A defect of memory from paſſion, natural weakneſs, &c. ſo that the proper word does not occur readily, alſo occaſions ſtammering, and, like all other modes of ſpeaking, it is caught, in ſome caſes, by imitation.

Sometimes ſtammering takes place only in the utterance of ſuch words as begin with certain letters, which are generally ſome of the labial or guttural conſonants, as *b*, *p*, *m*, *c*, *g*, &c. Some perſons, on the contrary, ſtammer in the utterance of all words indiſcriminately, with whatever letter they begin, whether they be vowel or conſonant, at certain times only; as *e. g.* when the ſpeaker is placed in any ſituation that occaſions hurry or embarraſſment. Agreeably to the obſervations already made, we find that perſons of great nervous irritability, and lively conſciouſneſs, are moſt liable to ſtammering. This ſort of impediment is a bad habit, founded upon this conſtitutional ſuſceptibility: and in attempting to remove ſtammering, while every attention ſhould be paid to ſuch means as phyſical and medical ſcience will point out for the ſtrengthening of the corporeal ſyſtem, it is of the utmoſt importance to induce the perſons affected with it to reaſon on the ſubject. Let them practiſe the formation of the component parts of words, (that is, ſimple vocal ſounds and the powers of the conſonants,) ſingly, and in combination, alternately, till a facility and habit of ſubjecting the muſcles concerned in ſpeech to the will be acquired or regained. They ſhould be accuſtomed to conſider that which is true in fact, that the organs of ſpeech are moved by muſcles which, from the laws of animal economy, are the inſtruments of the will; though we are conſcious of an act of the will only at the commencement of ſuch actions.

To counteract ſtammering, therefore, we muſt appeal to the underſtanding, and endeavour to arouſe the will into vigilant and vigorous controul of the muſcles. When a heſitation happens, let a volition or direct act of this power take place: firſt to ceaſe muſcular motion altogether, and then to commence a new ſeries. The greateſt deliberation and recollection ſhould be uſed in ordinary converſation; and the act of ſpeaking, as ſuch ſhould be conſtantly preſent to the mind, till the wrong habit be overcome, and the right ſo confirmed as to leave no room to apprehend a relapſe. The voice ſhould be carefully pitched at that tone which nature in the individual points out as eaſieſt to the organs, and moſt agreeable to the ear; and by no means ſhould a hurried pronunciation, or fictitious voice, be reſorted to. It ſhould be ſtudiouſly remembered, that we are accountable to no one for the innocent and decorous exerciſe of our muſcular powers—that over them we ourſelves alone ought to have controul—that ſpeech, on proper occaſions, is not only an innocent and a decorous, but, in the eyes of others, a neceſſary and an agreeable exerciſe of our muſcles. Why then be thrown into perturbation and confuſion, when we are to perform an action, confeſſedly in our power; and which others have not only no right to prevent, but are deſirous that we ſhould perform? If this train of reaſoning be fairly entered upon, many other arguments will ſuggeſt themſelves, and muſt inevitably produce good.

The following directions, with variations according to circumſtances, will be found to be attended with advantage, if duly and perſeveringly complied with.

In order to raiſe a voice, or that material of which ſpeech is formed, let the vowels be practiſed in a natural key, but with firmneſs and ſtrength, for ten minutes or a quarter of an hour, at leaſt, every morning. Then let the powers of the conſonants be formed, in their order, ſingly, and variouſly combined with the vowels.

After a little reſt, if imagination ſupply a ſubject, by all means let an imaginary converſation take place for twenty minutes, half an hour, or even an hour, in a firm and natural tone of voice, uſing every effort of fancy, to ſuppoſe it directed to perſons indiſcriminately; that is, ſometimes to ſervants, ſometimes to equals in age and rank, and ſometimes to elders, or thoſe conſidered as ſuperior in conſequence and rank in ſociety, from whatever cauſe. But if imagination do not furniſh a topic, then let the time be ſpent in reading, in a tone as nearly approaching to the eaſe of familiar converſation as poſſible, taking care to manage the fancy as above. This will furniſh the leſſon :—and after an interval of a few hours, the ſame ſort of converſation or reading ſhould be repeated, two or three times more in the courſe of a day. And on mixing with real auditors, every exertion ſhould be made to aſſociate the ideas of their imaginary, with their actual preſence.

Theſe directions, it will be perceived, are founded upon the principle of the aſſociation of ideas; than which a more powerful principle, in the formation of human habits, cannot be conceived.

An ingenious writer, whoſe obſervations we are now citing, is of opinion, that it may be laid down as an incontrovertible poſition, that perſons poſſeſſing an ordinary mental capacity, with an adequate ſhare of induſtry and ſtrength, may *certainly* overcome the habit of ſtammering, by means ſuch as here pointed out. See "Inſtruction of the Deaf and Dumb," &c. by Joſeph Watſon, LL.D. 2 vols. 8vo. 1809.

STAMNOS, an urn, or veſſel for holding water. Some authors have made it ſignify the bucket-head, as it is called, of thoſe alembics which have no worm, but are cooled about the head by this means.

STAMP, a term uſed in ſome places for a weir, or water-fall.

STAMP-*Duties*, are a tax impoſed upon all parchment and paper, on which any legal proceedings, or private inſtruments of almoſt any nature whatſoever are written; and alſo upon licences for retailing wines of all denominations; upon all almanacs, newſpapers, advertiſements, cards, dice, and pamphlets containing leſs than ſix ſheets of paper. Theſe impoſts are very various, according to the nature of the thing ſtamped.

This tax, though in many inſtances very burdenſome, is of ſervice to the public in general, by authenticating inſtruments, rendering it much more difficult than formerly to forge deeds of any ſtanding; ſince, as the officers of this branch of the revenue vary their ſtamps frequently, by marks perceptible to none but themſelves, a man that would forge a deed of king William's time muſt know, and be able to counterfeit the ſtamp of that date alſo.

The firſt inſtitution of the ſtamp-duties was by ſtatute 5 & 6 Will. and Mar. c. 21; and they have ſince, in many inſtances, been increaſed by ſubſequent ſtatutes very far above their original amount. It would far exceed the limits of this work to recite all the duties of this kind that already exiſt; but it may not be improper to mention ſome of thoſe that are moſt common.

By 44 Geo. III. c. 98. the ſeveral ſtamp-duties granted by any act of parliament then in force were repealed, and upon every almanac or calendar, for any time not exceeding one year, was impoſed the duty of 1*s.*; for each and every year for which almanacs or calendars for ſeveral years ſhall be made, publiſhed, or intended, 1*s.*; and for a perpetual almanac or calendar, 10*s.* The calendar or perpetual almanac in any bible or common prayer book is ſpecially exempted. Books or pamphlets ſerving the purpoſe of an almanac or calendar are ſubject to the ſame duty reſpectively, and to the ſame exemptions. (See ALMANAC.) For the ſtamp-duty on newſpapers and pamphlets, ſee NEWSPAPERS.

By 44 Geo. III. c. 98. the ſeveral duties before impoſed upon cards and dice made in Great Britain were repealed, and a new duty was impoſed upon ſuch cards and dice, *viz.* upon every pack of cards which ſhall be made fit for ſale or uſe in Great Britain, 2*s.* 6*d.*; and upon every pair of dice fit for ſale or uſe in Great Britain, 1*l.* See CARDS.

In one of the acts, *viz.* 10 Ann. c. 19. relating to the ſtamp-duties, which are become in proceſs of time very numerous and intricate, there is a clauſe which brings all the reſt within the juriſdiction of the juſtices of the peace, and it is as follows: Two juſtices reſiding near the place where any pecuniary forfeitures not exceeding 20*l.*, or any act touching any of the duties under the management of the commiſſioners of the duties on ſtamped vellum, parchment, and paper, ſhall be incurred, or any offence againſt any of the ſame acts ſhall be committed in any wiſe relating to the ſame duties, by which any ſum of money only may be forfeited, may hear and determine the ſame; who ſhall, on information or complaint, within a year after the ſeizure made or offence committed, ſummon the party accuſed, and witneſſes; and may iſſue warrants for levying the penalties by diſtreſs and ſale, if not redeemed in ſix days. The ſaid juſtices may at pleaſure mitigate the penalties, the charges being firſt allowed; ſo that they do not reduce the penalty to leſs than double duty, over and above the ſaid charges. The juſtice, before whom the offending perſon is convicted, ſhall levy the penalty, and apply the ſame as the act directs; and in default of ſufficient direction, the ſame ſhall be applied, half to the king, and half to the perſon who ſhall proſecute for the ſame, if within ſix months after the offence is committed; but if after ſix months, the whole ſhall go to the king (26 Geo. III. c. 82.); which conviction ſhall be filed by the clerk of the peace, and ſhall not be removable by certiorari into any other court; but nevertheleſs ſubject to appeal to the quarter-ſeſſions, in ſuch manner as by any former act is directed. But now by the ſtat. 44 Geo. III. c. 98. ſ. 10. no action or information ſhall be commenced or filed in any court, or before any juſtice or juſtices of the peace, for any penalty or forfeiture under any of the ſtamp acts, but in the name of the attorney-general, or in the name of the ſolicitor or ſome other officer of the ſtamp-duties. And all penalties and forfeitures under the ſtamp-acts are to be applied to the uſe of the king, &c.; but the commiſſioners of the ſtamps may give ſuch part of the penalty to the informer as they may think expedient.

By the 44 Geo. III. c. 98. all the duties and drawbacks under the care of the commiſſioners of the ſtamps ſhall ceaſe from October 10, 1804, except as to the recovering of any penalties incurred previouſly thereto; and after that time certain duties are made payable, as ſpecified in the ſchedules to that act annexed. By the 48 Geo. III. c. 149. the ſeveral duties in the ſchedule (A) to the former act annexed are repealed, excepting in certain caſes.

By 55 Geo. III. c. 184. the duties granted by 48 Geo. III. c. 149. are repealed, together with the duties on pawnbrokers' licences (44 Geo. III. c. 98.), and thoſe on policies of inſurance in the Weſt Indies, or elſewhere beyond the ſeas, granted in the 50th year of his majeſty's reign, and the per-centage duty on inſurances againſt fire, granted by 44 Geo. III. c. 98, all arrears excepted. The duties ſpecified in the ſchedule annexed to 55 Geo. III. c. 184. are to be levied, and are committed to the management of the commiſſioners of ſtamps, who are to provide proper ſtamps, &c. By the ſame act, any perſon actually forging ſtamps, &c. and his aider or abettor, being lawfully convicted, ſhall ſuffer death as a felon, without benefit of clergy. It is further enacted, that all powers and proviſions of former acts, together with fines, forfeitures, &c. ſhall extend to this act. The proviſions of former acts reſpecting agreements ſhall be applied only to thoſe that are charged with 1*l.*; and it is enacted, that the agreements charged with a duty of 1*l.* 15*s.* ſhall be ſubject to the ſame regulations as deeds hereby charged with a like duty. This act provides, that inſtruments having wrong ſtamps, but of ſufficient value, ſhall be valid; except in caſes where the ſtamps uſed on ſuch inſtruments ſhall have been ſpecially appropriated to any other inſtrument, by having its name on the face thereof. It is further enacted, that the penalty for making, accepting, or paying bills of exchange, &c. without being duly ſtamped, ſhall be the forfeiture of 50*l.*; and the penalty of poſt-dating bills of exchange, &c. ſhall be the forfeiture of 100*l.* The penalty for iſſuing unſtamped drafts on bankers, without ſpecifying the place where iſſued, or if poſt-dated, is 100*l.* The penalty for receiving ſuch drafts is 20*l.*, and on bankers for paying them, 100*l.* It is enacted, that promiſſory notes to bearer on demand, not exceeding 100*l.*, may be re-iſſued by the original makers, without further duty; nor ſhall ſuch notes be liable to further duty, though re-iſſued by certain perſons, not ſtrictly the original makers. Notes re-iſſuable under 48 or 53 Geo. III. are to continue re-iſſuable till the end of three years from the date; the penalty on each fraud in the buſineſs being 50*l.* The penalty on iſſuing promiſſory notes for the payment of money to the bearer on demand, with printed dates, is 50*l.* Notes re-iſſuable for a limited period are to be cancelled, on payment afterwards; and notes not re-iſſuable are to be cancelled immediately on payment. The penalty for re-iſſuing notes, &c. contrary to law, and for not cancelling them, is 50*l.*: the penalty for taking notes, &c. re-iſſued contrary to law, is 20*l.* However, notes and bills of the bank of England are exempted from ſtamp-duty; and any ſuch notes may be re-iſſued after payment, as often as it ſhall be thought fit. The compoſition annually payable by the governor and company of the bank of England, for the duties on their bills and notes, is the ſum of 3500*l.* for every million, and after that rate for half a million, but not for a leſs ſum than half a million, of the ſaid averagement or value of their ſaid notes and bank poſt-bills in circulation: but when the governor and company reſume their payments in caſh, a new averagement for the compoſition on account of ſtamp-duties ſhall be ſubmitted to parliament. It is alſo enacted, that the bank of Scotland, and royal bank of Scotland, and Britiſh linen company, may iſſue ſmall notes on unſtamped paper, accounting for the duties.

It is further enacted, that re-iſſuable notes are not to be iſſued by bankers or others, without a licence; which licences are ſubject to certain regulations, ſpecified in the act. But no banker ſhall take out more than four licences for any number of towns in Scotland. Several towns in England may, in certain caſes, be included in one licence. Perſons applying for licences are to deliver ſpecimens of their notes; and the penalty for iſſuing notes without licence is 100*l.*

It is enacted, that promiſſory notes made out of Great Britain are not to be negociable, unleſs ſtamped; and the penalty on circulating ſuch notes is 20*l.* for each.

The duty on fire-inſurances is to be collected by the companies undertaking the ſame, who ſhall render to the commiſſioners of ſtamps quarterly accounts, making up ſuch accounts to their own quarter-days. Theſe companies have an allowance for collecting the duties of 4*l.* *per cent.* at the head office in London or Weſtminſter, and of 5*l.* *per cent.* elſewhere.

The penalty, by this act, for not proving wills, or taking letters of adminiſtration within a given time, *viz.* ſix calendar months after the deceaſe of any perſon, or two calendar months after the termination of any depending ſuit, is a forfeiture of 100*l.*, and 10*l.* *per cent.* on the duty. Eccleſiaſtical courts are forbidden to grant probates or letters of adminiſtration, without affidavit of the value of effects; and ſuch affidavits are to be free of ſtamp-duty, and to be tranſmitted to commiſſioners of ſtamps; the penalty for neglect being 50*l.* Proviſion is made for adjuſting the ſtamp-duty, when it is either too high or too low. The penalty on executors, &c. for not paying the full duty on probates, &c. within a given time after diſcovery of a deficiency, is 100*l.*, and 10 *per cent.* on the deficient duty. The commiſſioners of ſtamps may give credit for the duty on probates and letters of adminiſtration, in certain circumſtances; and may extend the credit, if neceſſary. A return of duty on probates, &c. is to be made in reſpect of debts, if claimed within three years.

Articles of confectionary are exempted from ſtamps, unleſs they be avowedly ſold as medicines. The money accruing from all the duties ariſing from this act is to be paid to the receiver-general, and by him into the exchequer.

The ſchedule belonging to this act conſiſts of three parts: the *firſt* containing the duties on admiſſions to offices, &c.; on inſtruments of conveyance, contract, obligation, and ſecurity for money; on deeds in general; and on other inſtruments not included under the following heads. The *ſecond* part contains the duties on law proceedings. The *third* part contains the duties on probates of wills and letters of adminiſtration; on confirmations of teſtaments; on inventories to be exhibited in the commiſſary courts of Scotland; on legacies out of real or perſonal, heritable or moveable eſtates; and on ſucceſſions to perſonal or moveable eſtates upon inteſtacy. Out of this maſs of matter we ſhall content ourſelves with ſelecting thoſe articles that are moſt common and moſt intereſting; referring for thoſe of more rare occurrence, or of leſs general intereſt, to the act itſelf.

Under the *firſt* part we ſhall begin with the duty on the admiſſion of any perſon to act as an advocate in any of the eccleſiaſtical courts, or in the high court of admiralty, or in any of the courts of juſtice in Scotland, which is 50*l.*; and the ſame ſum on the admiſſion of any perſon to the degree of barriſter at law in either of the inns of court in England. On admiſſion of any perſon to act as an attorney, ſolicitor, or proctor, in any court in England; or as a ſworn clerk, clerk in court, or other clerk or officer in any court in England, whoſe buſineſs and emoluments depend, like thoſe of an attorney or ſolicitor, on his being retained and employed by clients or ſuitors, the duty is 25*l.* Theſe duties are ſubject to certain regulations, which we ſhall not detail. The ſame ſum is alſo payable on the admiſſion of any perſon to act as a writer to the ſignet, or as a ſolicitor, &c. in any court in Scotland. For the admiſſion of any perſon to act as a ſolicitor, &c. in the court of ſeſſion, juſticiary, or commiſſion of teinds in Scotland, who ſhall not have ſerved a clerkſhip for five years, to a writer to the ſignet, or a ſolicitor, under regular articles, which ſhall have paid the ſtamp-duty payable by law, his admiſſion ſhall be charged with a *further* duty of 60*l.*; and if any perſon be admitted to act as a procurator or ſolicitor in the high court of admiralty in Scotland, the commiſſary court, or any inferior court in Scotland, without having ſerved a five years' clerkſhip or apprenticeſhip, &c. he ſhall be charged with a further duty of 30*l.* Theſe payments are ſubject to certain exemptions. For admiſſion of any perſon as a maſter in ordinary in chancery, or as one of the ſix clerks, or one of the curſitors of the court of chancery in England, or as a ſworn clerk, &c. in any court in Great Britain, the duty, where the ſalary, fees, &c. ſhall not amount to 50*l.* a year, is 2*l.*; between 50*l.* and 100*l.*, 4*l.*; from 100*l.* to 200*l.*, 6*l.*; from 200*l.* to 300*l.*, 12*l.*; from 300*l.* to 500*l.*, 25*l.*; from 500*l.* to 750*l.*, 35*l.*; from 750*l.* to 1000*l.*, 50*l.*; from 1000*l.* to 1500*l.*, 75*l.*; from 1500*l.* to 2000*l.*, 100*l.*; from 2000*l.* to 3000*l.*, 150*l.*; and from 3000*l.* upwards, 200*l.* The duty for admiſſion

miſſion as a notary public in England, is 30*l.*; and in Scotland, 20*l.*; for admiſſion to be a member of either of the four inns of court in England, 25*l.*; into either of the ſocieties called inns of chancery, 3*l.*; into the college of phyſicians in England or Scotland, 25*l.*; as a licentiate, 15*l.*; on matriculation in either of the Engliſh univerſities, 1*l.*; to the degree of a bachelor of arts in either Engliſh univerſity, 3*l.* when conferred in ordinary courſe, and 5*l.* when conferred by ſpecial grace, or royal mandate, or by reaſon of nobility, or out of the ordinary courſe; to any other degree in either Engliſh univerſity, for regiſtry, in the ordinary courſe, 6*l.*, out of ſuch courſe, 10*l.*; to the degree of doctor of medicine in either of the univerſities of Scotland, 10*l.*

For the admiſſion of any perſon into any corporation, in reſpect of birth, apprenticeſhip, or marriage, the duty is 1*l.*; but upon any other ground, 3*l.* For an affidavit, the ſtamp-duty is 2*s.* 6*d.*, ſubject to various exemptions. For an agreement, or memorandum of the ſame, made in England under hand only, or in Scotland without any clauſe of regiſtration, on a matter of the value of 20*l.*, or upwards, containing no more than 1080 words, 1*l.*; for more than 1080 words, 1*l.* 15*s.*; and for every quantity of 1080 words after the firſt, a progreſſive duty of 1*l.* 5*s.* This duty is ſubject to ſeveral general exemptions.

On the appointment of a chaplain, empowering to hold two eccleſiaſtical benefices in England, the duty is 2*l.*; on the appointment or deputation of a game-keeper, 1*l.* 15*s.* On the appraiſement or valuation of any eſtate or effects, or any intereſt therein, or its annual value, or of any dilapidation, or of any repairs, &c. if the valuation ſhall not exceed 50*l.*, 2*s.* 6*d.*; from 50*l.* to 100*l.*, 5*s.*; from 100*l.* to 200*l.*, 10*s.*; from 200*l.* to 500*l.*, 15*s.*; and above 500*l.*, 1*l.* For the indenture of apprenticeſhip or clerkſhip (articles of clerkſhip to attornies excepted), when the ſum of money paid to the maſter or miſtreſs ſhall not amount to 30*l.*, 1*l.*; from 30*l.* to 50*l.*, 2*l.*; from 50*l.* to 100*l.*, 3*l.*; from 100*l.* to 200*l.*, 6*l.*; from 200*l.* to 300*l.*, 12*l.*; from 300*l.* to 400*l.*, 20*l.*; from 400*l.* to 500*l.*, 25*l.*; from 500*l.* to 600*l.*, 30*l.*; from 600*l.* to 800*l.*, 40*l.*; from 800*l.* to 1000*l.*, 50*l.*; from 1000*l.* and upwards, 60*l.* For an indenture, without any conſideration to the maſter or miſtreſs, containing more than 1080 words, 1*l.*; and for more than that quantity, 1*l.* 15*s.* Theſe indentures are ſubject to exemptions in favour of poor children apprenticed. For articles of clerkſhip, in order to admiſſion as an attorney or ſolicitor in any of his majeſty's courts at Weſtminſter, 120*l.*; in any of the courts of the great ſeſſions in Wales, or of the counties palatine of Cheſter, Lancaſter, and Durham, or in any other court of record in England, holding pleas, in which the debt or damage amounts to 40*s.*, 60*l.*; and for any duplicate of ſuch articles, 1*l.* 15*s.* With a view to admiſſion as a ſworn clerk in the office of the ſix clerks, or as a ſworn clerk, &c. in the office of pleas, &c. in England, 120*l.*; and for any duplicate, 1*l.* 15*s.* For articles of clerkſhip, in order to admiſſion as a proctor, 120*l.*; and for a duplicate, 1*l.* 15*s.* For indenture of clerkſhip, in order to admiſſion as a writer to the ſignet, or ſolicitor in any of the courts of ſeſſion, &c. in Scotland, 60*l.*; and for a duplicate, 1*l.* 15*s.* For indenture of clerkſhip, in order to admiſſion to act as a procurator or ſolicitor in the high court of admiralty, the commiſſary court at Edinburgh, or any other inferior court in Scotland, 30*l.*; and for any duplicate, 1*l.* 15*s.*

For an inland bill of exchange, on demand or otherwiſe, not exceeding two months after date, or 60 days after ſight, the duty for any ſum amounting to 40*s.*, and not exceeding 5*l.* 5*s.*, is 1*s.*; from 5*l.* 5*s.* to 20*l.*, 1*s.* 6*d.*; from 20*l.* to 30*l.*, 2*s.*; from 30*l.* to 50*l.*, 2*s.* 6*d.*; from 50*l.* to 100*l.*, 3*s.* 6*d.*; from 100*l.* to 200*l.*, 4*s.* 6*d.*; from 200*l.* to 300*l.*, 5*s.*; from 300*l.* to 500*l.*, 6*s.*; from 500*l.* to 1000*l.*, 8*s.* 6*d.*; from 1000*l.* to 2000*l.*, 12*s.* 6*d.*; from 2000*l.* to 3000*l.*, 15*s.*; and exceeding 3000*l.*, 1*l.* 5*s.* For an inland bill of exchange, to bearer or order, exceeding two months after date, or 60 days after ſight, for any ſum from 40*s.* to 5*l.* 5*s.*, 1*s.*; from 5*l.* 5*s.* to 20*l.*, 2*s.*; from 20*l.* to 30*l.*, 2*s.* 6*d.*; from 30*l.* to 50*l.*, 3*s.* 6*d.*; from 50*l.* to 100*l.*, 4*s.* 6*d.*; from 100*l.* to 200*l.*, 5*s.*; from 200*l.* to 300*l.*, 6*s.*; from 300*l.* to 500*l.*, 8*s.* 6*d.*; from 500*l.* to 1000*l.*, 12*s.* 6*d.*; from 1000*l.* to 2000*l.*, 15*s.*; from 2000*l.* to 3000*l.*, 1*l.* 5*s.*; and above 3000*l.*, 1*l.* 10*s.* The duty for a foreign bill of exchange, drawn ſingly and not in a ſet, the ſame duty as on an inland bill of the ſame amount and tenor. The duty on foreign bills of exchange, drawn in ſets according to the cuſtom of merchants, is for every bill of each ſet, where the ſum made payable doth not exceed 100*l.*, 1*s.* 6*d.*; from 100*l.* to 200*l.*, 3*s.*; from 200*l.* to 500*l.*, 4*s.*; from 500*l.* to 1000*l.*, 5*s.*; from 1000*l.* to 2000*l.*, 7*s.* 6*d.*; from 2000*l.* to 3000*l.*, 10*s.*; and for more than 3000*l.*, 15*s.* The bills exempt from the preceding and all other ſtamp-duties, are thoſe iſſued by the governor and company of the bank of England, navy-bills, bills for the pay and allowances of his majeſty's land forces, and ſome others. (See PROMISSORY *Notes.*) A bill of lading is chargeable with a duty of 3*s.* A bond in England, and perſonal bond in Scotland, given as a ſecurity for the payment of any definite ſum of money, is chargeable, when the ſum does not exceed 50*l.*, with a duty of 1*l.*; from 50*l.* to 100*l.*, 1*l.* 10*s.*; from 100*l.* to 200*l.*, 2*l.*; from 200*l.* to 300*l.*, 3*l.*; from 300*l.* to 500*l.*, 4*l.*; from 500*l.* to 1000*l.*, 5*l.*; from 1000*l.* to 2000*l.*, 6*l.*; from 2000*l.* to 3000*l.*, 7*l.*; from 3000*l.* to 4000*l.*, 8*l.*; from 4000*l.* to 5000*l.*, 9*l.*; from 5000*l.* to 10,000*l.*, 12*l.*; from 10,000*l.* to 15,000*l.*, 15*l.*; from 15,000*l.* to 20,000*l.*, 20*l.*; and exceeding 20,000*l.*, 25*l.* For a bond in England, and a perſonal bond in Scotland, given as a ſecurity for the transfer, or re-transfer of any ſhare in any of the government parliamentary ſtocks or funds, or in the ſtock and funds of the bank of England, or Eaſt India company, or of the South-ſea company, the duty is the ſame as on a bond for a ſum of money, equal to the value of the ſtock or fund ſecured, according to its average price, on the day of the date of the bond, or on either of the ten days preceding.

For a bond in England, and perſonal and heritable bond in Scotland, given as a ſecurity for the payment of any annuity, except upon the original creation and ſale thereof, or of any ſum or ſums of money at ſtated periods, not being intereſt for any principal ſum, nor rent reſerved or payable upon any leaſe or tack, for any definite and certain term, ſo that the total amount of the money to be paid can be previouſly aſcertained, the ſame duty as on a bond of the like nature, for the payment of a ſum of money equal to ſuch total amount. For a ſimilar bond, for the payment of an annuity, &c. for any indefinite period, or the term of life, ſo that the whole money to be paid cannot be previouſly aſcertained, if the annuity, or ſums ſecured, ſhall not amount to 10*l.* *per annum*, 1*l.*; from 10*l.* to 50*l.* *per annum*, 2*l.*; from 50*l.* to 100*l.*, 3*l.*; from 100*l.* to 200*l.*, 4*l.*; from 200*l.* to 300*l.*, 5*l.*; from 300*l.* to 400*l.*, 6*l.*; from 400*l.* to 500*l.*, 7*l.*; from 500*l.* to 750*l.*, 9*l.*; from 750*l.* to 1000*l.*, 12*l.*; from 1000*l.* to 1500*l.*, 15*l.*; from 1500*l.* to 2000*l.*, 20*l.*; and from 2000*l.* *per annum* and upwards, 25*l.* The duties on various kinds of bonds are ſubject to various exemptions and regulations, for which we refer to the ſtatute. For a yearly certificate taken out by every perſon admitted as an attorney or ſolicitor, and as a proctor, in England, and by every perſon admitted as a writer to the ſignet, ſolicitor, agent, attorney, or procurator, in any of the courts of Scotland; and by every ſworn clerk, &c. and any other clerk or officer in any of the courts aforeſaid, who ſhall act, in expectation of any fee or reward, as an attorney, ſolicitor, agent, proctor, procurator, or notary public, though not admitted or enrolled as ſuch, if he ſhall reſide in the city of London, or city of Weſtminſter, or within the limits of the two-penny poſt in England, or within the city or ſhire of Edinburgh, who has been in poſſeſſion of his office for three years or upwards, 12*l.*, or if he has not been in poſſeſſion ſo long, 6*l.*; or if he ſhall reſide elſewhere, in the firſt circumſtance above ſtated, 8*l.*, and in the ſecond, 4*l.* For a certificate taken out yearly by a member of one of the four inns of court in England, who acts as a conveyancer, ſpecial pleader, draftſman in equity, or otherwiſe, if he ſhall reſide in the city of London, &c. as before ſtated, 12*l.*; or if he ſhall reſide elſewhere, 8*l.* The exemptions comprehend ſergeants at law and barriſters; attornies, ſolicitors, proctors, and notaries public; and other perſons acting as ſuch by virtue of any office or appointment, taking out certificates in theſe characters; and public officers preparing deeds, &c. by virtue of their office. A certificate of marriage, that of any common ſeaman, marine, or ſoldier excepted, is chargeable with a duty of 5*s.*; and ſo is the certificate of a perſon's having received the holy ſacrament. The duty upon a charter-party is 1*l.* 15*s.*; that upon collation by an archbiſhop or biſhop to any eccleſiaſtical benefice or promotion of 10*l.* or upwards yearly value in the king's books, is 20*l.*; that of collation to any other eccleſiaſtical benefice, &c. in England, is 10*l.*; that of collation, or admiſſion by any preſbytery or competent authority, to any eccleſiaſtical benefice in Scotland, is 2*l.* For the duties on different kinds and modes of conveyance, ſee the ſtatute. The duty on a debenture or certificate for entitling a perſon to receive a drawback of duties in the cuſtoms or exciſe, or bounty payable out of the revenue of either, if the ſame ſhall not exceed 100*l.*, is 5*s.*; from 100*l.* to 200*l.*, 10*s.*; from 200*l.* to 500*l.*, 1*l.*; and above 500*l.*, 2*l.* For a declaration of truſt, &c. the duty is 1*l.* 15*s.* For every ſkin or piece of vellum, &c. upon which ſhall be written the exemplification or conſtat under the great ſeal of the united kingdom of Great Britain and Ireland, of any letters patent or grant, the duty is 5*l.*

For a faculty from the archbiſhop of Canterbury, or the maſter of the faculties for the time being, or from the guardian of the ſpiritualities during a vacancy of the archbiſhop's ſee, not otherwiſe charged, the duty is 30*l.* For a grant or letters patent under the great ſeal, or the ſeal of the county palatine of Lancaſter, or the ſeal kept and uſed in Scotland, of the honour or dignity of a duke, 350*l.*; of a marquis, 300*l.*; of an earl, 250*l.*; of a viſcount, 200*l.*; of a baron, 150*l.*; of a baronet, 100*l.*; of a congé d'elire for any dean and chapter, for the election of an archbiſhop or biſhop, 30*l.*; of the royal aſſent to or ſignification of ſuch election, or of the nomination and preſentation by his majeſty, in default of ſuch election, of any perſon to be an archbiſhop or biſhop, 30*l.*; of or for the reſtitution of the temporalties to any archbiſhop or biſhop, 30*l.*; of any other honour or franchiſe, &c. to any perſon or perſons, body or bodies politic or corporate, 30*l.*; and if ſuch grant or letters patent are contained in more than one ſkin, piece of vellum, &c., then for every ſkin, ſheet, or piece thereof, after the firſt, a progreſſive duty of 20*l.* For a grant or warrant of precedence to take rank among nobility, under his majeſty's ſign manual, 100*l.*; for a grant or licence, under the ſign manual, to take and uſe a ſurname and arms, or a ſurname only, in compliance with any will or ſettlement, 50*l.*; for arms to the ſame, on voluntary application, 10*l.*; and for grant of arms, or armorial enſigns only, 10*l.* For a grant, under the great ſeal, &c. of any definite ſum of money, not amounting to 100*l.*, 1*l.* 10*s.*; from 100*l.* to 250*l.*, 4*l.*; from 250*l.* to 500*l.*, 10*l.*; from 500*l.* to 750*l.*, 20*l.*; from 750*l.* to 1000*l.*, 30*l.*; from 1000*l.* and upwards, for every 500*l.*, 5*l.*

The duty on a grant of any annuity or penſion, not amounting to 100*l.* *per annum*, is 1*l.* 10*s.*; from 100*l.* to 200*l.*, 4*l.*; from 200*l.* to 400*l.*, 10*l.*; from 400*l.* to 600*l.*, 20*l.*; from 600*l.* to 800*l.*, 30*l.*; from 800*l.* to 1000*l.*, 40*l.*; from 1000*l.* and upwards, 50*l.* For his majeſty's grant of any office or employment, by letters patent, deed, or other writing, the profits of which do not amount to 50*l.* *per annum*, 2*l.*; from 50*l.* to 100*l.*, 4*l.*; from 100*l.* to 200*l.*, 6*l.*; from 200*l.* to 300*l.*, 12*l.*; from 300*l.* to 500*l.*, 25*l.*; from 500*l.* to 750*l.*, 35*l.*; from 750*l.* to 1000*l.*, 50*l.*; from 1000*l.* to 1500*l.*, 75*l.*; from 1500*l.* to 2000*l.*, 100*l.*; from 2000*l.* to 3000*l.*, 150*l.*; from 3000*l.* and upwards, 200*l.*

For inſtitution to any eccleſiaſtical benefice in England upon preſentation, 2*l.*; upon petition of the patron to be admitted, if the benefice or promotion be of the yearly value of 10*l.* and upwards in the king's books, 30*l.*; or if the ſame ſhall be of any other deſcription, 15*l.*

The duty on a letter of attorney, made by a petty officer, ſeaman, marine, or ſoldier ſerving as a marine, for receiving prize money, is 1*s.*, for receiving wages, 1*l.* For a letter of attorney for the ſale, transfer, acceptance, or receipt of dividends in any of the government ſtocks or funds, 1*l.*; for that of any other kind, or commiſſion or factory, 1*l.* 10*s.*; and if more than 1080 words be uſed, a progreſſive duty for every 1080 words, after the firſt, of 1*l.* For a letter of licence from creditors to a debtor, the duty is 1*l.* 15*s.*; and a progreſſive duty for every 1080 words above the firſt number, of 1*l.* 5*s.*: for letters of marque and repriſal, 5*l.*: for licence for marriage in England, if ſpecial, 5*l.*; if not ſpecial, 10*s.*: for licence to uſe the occupation of an appraiſer, taken out yearly, 10*s.*: for a banker or any other perſon who ſhall iſſue any promiſſory notes for money payable to the bearer on demand, and allowed to be re-iſſued, 30*l.*: for exerciſing the trade of a pawnbroker within the cities of London and Weſtminſter, or within the limits of the two-penny poſt, 15*l.*; and elſewhere, 7*l.* 10*s.* For policy of aſſurance on life or lives, if the ſum inſured ſhall not amount to 500*l.*, 1*l.*; from 500*l.* to 1000*l.*, 2*l.*; from 1000*l.* to 3000*l.*, 3*l.*; from 3000*l.* to 5000*l.*, 4*l.*; from 5000*l.* and upwards, 5*l.* For policy of inſurance from loſs or damage by fire to goods, &c. 3*s.* *per cent. per annum*. For policy of inſurance on any ſhip or veſſel, or any goods on board, &c. where the premium ſhall not exceed the rate of 20*s.* *per cent.* on the ſum inſured, if the whole ſum does not exceed 100*l.*, the ſtamp-duty is 1*s.* 3*d.*; if the whole ſum ſhall exceed 100*l.*, then for every 100*l.*, and alſo for any fractional part of 100*l.*, 1*s.* 3*d.*; and where the premium ſhall exceed the rate of 20*s.* *per cent.* on the ſum inſured, if the whole ſum inſured ſhall not exceed 100*l.*, 2*s.* 6*d.*; if it ſhall exceed 100*l.*, then for every 100*l.*, and alſo for any fractional part of 100*l.*, 2*s.* 6*d.* If the inſurance be made upon any ſhip or veſſel, or goods, or freight, for any other voyage beſides that above mentioned,

tioned, from any part in the united kingdom or the adjacent iſlands, to any other part in the ſaid kingdom or iſlands, or for any certain term or period of time not exceeding twelve calendar months, if the premium be 20*s.* *per cent.* on the ſum inſured, and the whole ſum do not exceed 100*l.*, the duty is 2*s.* 6*d.*; but if it ſhall exceed 100*l.*, then for every 100*l.*, and for any fractional part, 2*s.* 6*d.*: and if the premium exceed 20*s.* *per cent.* on the ſum inſured, if the whole ſum ſhall not exceed 100*l.*, the duty is 5*s.*; and if it ſhall exceed 100*l.*, then for every 100*l.*, and any fractional part of 100*l.*, of which the ſame ſhall conſiſt, 5*s.*

For a preſentation by his majeſty, or by any patron, to any eccleſiaſtical benefice, &c. of the yearly value of 10*l.* or upwards in the king's books, the duty is 20*l.*; and to any other eccleſiaſtical benefice or promotion in England, 10*l.* For a deed of procuration, 1*l.* 10*s.* Of PROMISSORY *Notes* we have already given an account under that article; but the act, the proviſions of which we are now reciting, has repealed the 48th of Geo. III. and made ſome addition to the ſtamp-duties. The note for payment of any ſum of money to the bearer on demand is chargeable, for 1*l.* 1*s.* with a duty of 5*d.*; from 1*l.* 1*s.* to 2*l.* 2*s.* with 10*d.*; from 2*l.* 2*s.* to 5*l.* 5*s.* with 1*s.* 3*d.*; from 5*l.* 5*s.* to 10*l.*, with 1*s.* 9*d.*; from 10*l.* to 20*l.*, with 2*s.*; from 20*l.* to 30*l.*, with 3*s.*; from 30*l.* to 50*l.*, with 5*s.*; from 50*l.* to 100*l.*, with 8*s.* 6*d.* The promiſſory note for payment in any other manner, &c. but not exceeding two months after date, or 60 days after ſight, from 40*s.* to 5*l.* 5*s.*, is chargeable with a duty of 1*s.*; from 5*l.* 5*s.* to 20*l.*, 1*s.* 6*d.*; from 20*l.* to 30*l.*, 2*s.*; from 30*l.* to 50*l.*, with 2*s.* 6*d.*; from 50*l.* to 100*l.*, with 3*s.* 6*d.* Thoſe notes either to the bearer on demand, or in any other manner, but not exceeding two months after date, or 60 days after ſight, are chargeable, from 100*l.* to 200*l.*, with a duty of 4*s.* 6*d.*; from 200*l.* to 300*l.*, with 5*s.*; from 300*l.* to 500*l.*, 6*s.*; from 500*l.* to 1000*l.*, 8*s.* 6*d.*; from 1000*l.* to 2000*l.*, 12*s.* 6*d.*; from 2000*l.* to 3000*l.*, with 15*s.*; above 3000*l.* with 1*l.* 5*s.* Thoſe payable at any time exceeding two months after date, or 60 days after ſight, from 40*s.* to 5*l.* 5*s.*, are chargeable with a duty of 1*s.* 6*d.*; from 5*l.* 5*s.* to 20*l.*, 2*s.*; from 20*l.* to 30*l.*, 2*s.* 6*d.*; from 30*l.* to 50*l.*, 3*s.* 6*d.*; from 50*l.* to 100*l.*, 4*s.* 6*d.*; from 100*l.* to 200*l.*, 5*s.*; from 200*l.* to 300*l.*, 6*s.*; from 300*l.* to 500*l.*, 8*s.* 6*d.*; from 500*l.* to 1000*l.*, 12*s.* 6*d.*; from 1000*l.* to 2000*l.*, 15*s.*; from 2000*l.* to 3000*l.*, 1*l.* 5*s.*; exceeding 3000*l.*, 1*l.* 10*s.* (See PROMISSORY *Notes.*) For proteſt of a bill of exchange or promiſſory note, for any ſum under 20*l.*, 2*s.*; from 20*l.* to 100*l.*, 3*s.*; from 100*l.* to 500*l.*, 5*s.*; from 500*l.* upwards, 10*s.* For every ſheet on which a proteſt is written, after the firſt, a progeſſive duty of 5*s.* For receipts from 2*l.* to 5*l.*, 2*d.*; from 5*l.* to 10*l.*, 3*d.*; from 10*l.* to 20*l.*, 6*d.*; from 20*l.* to 50*l.*, 1*s.*; from 50*l.* to 100*l.*, 1*s.* 6*d.*; from 100*l.* to 200*l.*, 2*s.* 6*d.*; from 200*l.* to 300*l.*, 4*s.*; from 300*l.* to 500*l.*, 5*s.*; from 500*l.* to 1000*l.*, 7*s.* 6*d.*; from 1000*l.* upwards, 10*s.*; and in full of all demands, 10*s.* (See RECEIPT.) For ſettlement upon or for the benefit of any perſon or perſons, in poſſeſſion or reverſion, if the ſum ſhall not amount to 1000*l.*, the duty is 1*l.* 15*s.*; from 1000*l.* to 2000*l.*, 2*l.*; from 2000*l.* to 3000*l.*, 3*l.*; from 3000*l.* to 4000*l.*, 4*l.*; from 4000*l.* to 5000*l.*, 5*l.*; from 5000*l.* to 7000*l.*, 7*l.*; from 7000*l.* to 9000*l.*, 9*l.*; from 9000*l.* to 12,000*l.*, 12*l.*; from 12,000*l.* to 15,000*l.*, 15*l.*; from 15,000*l.* to 20,000*l.*, 20*l.*; from 20,000*l.* and upwards, 25*l.* For teſtimonial or certificate of the admiſſion of any perſon to the degree of bachelor of arts, in either of the Engliſh univerſities, 3*l.*; to any other degree, 10*l.* For transfer of any ſhare in bank ſtock, or South-ſea ſtock, 7*s.* 9*d.*; in the ſtock of the Eaſt India company, 1*l.* 10*s.*; in the ſtock of any other corporation, company, or ſociety, 1*l.* 10*s.*

For an account of the *ſecond* part of the ſchedule annexed to the 55th Geo. III. c. 184. containing the duties on law proceedings, we refer to the act itſelf.

The *third* part contains the duties on probates of wills and letters of adminiſtration, on confirmations of teſtaments, inventories, legacies, and ſucceſſions. The duties on probates of a will, and letters of adminiſtration with a will annexed, to be granted in England, confirmation of any teſtament and inventory to be recorded in any commiſſary court in Scotland, by the 55th Geo. III. which alters the amounts ſtated from 48 Geo. III. under PROBATE, are ſhewn in the following table:

For an account of legacies and ſucceſſions, as under the article Receipt, Schedule, part iii. with the following alteration agreeably to 55 Geo. III. c. 184; inſerting inſtead of 10th October 1808, the 31ſt day of Auguſt 1815; inſerting alſo in col. 2. line 13 from the bottom, after "deceaſed," or the father or mother, or any lineal anceſtor of the deceaſed; inſtead of *2l.* 10*s.* — *3l.*; inſtead of 4*l.* — *5l.*, and inſtead of *5l.* — *6l.*

Stamp-*Office*, an office under the direction of ſix commiſſioners, who are empowered to ſubſtitute inferior officers for the management of the ſtamp-duties. (5 Will. cap. 21. 9 & 10 Will. c. 25.) To this office belong a receiver-general, a comptroller, a ſecretary, and a number of clerks, &c. &c.

STAMPALIA, or Stampalæa, in *Geography*, formerly *Aſtypalæa*, properly ſignifying the ancient city, and called alſo *Pyrrha*, *Pilea*, and at length *Theon Trabeza*, *i. e.* the table of the gods, becauſe its ſoil is fertile, and it is almoſt every where enamelled with flowers, an iſland of the Archipelago, which, in the time of Pliny, was an independent country, and where Achilles had a temple, and that ſort of worſhip that was paid to valour, contributed to maintain among its inhabitants the energy neceſſary for people who are not willing to ſubmit to the yoke of a conqueror. From the irregular form of this iſland, it might be called the "Indented Iſland;" its ſhores preſenting a variety of points, or ſinuoſities, that form ſo many coves and bays fit for the anchorage of ſhips or boats, though we can ſcarcely reckon more than two harbours, the one to the ſouth, the other to the north. It is about ſix leagues in length, and only two in its greateſt breadth; it is not very lofty, nor has it any high mountains that can be diſcovered at a great diſtance. Its ſoil, as we have already ſaid, is fertile, being of that kind which is obſerved on plains and hills, and which does not extend to the tops of ſteep mountains. Stampalia is reckoned one of the moſt fertile iſlands of the Archipelago: its inhabitants experience the mildneſs of the climate and the goodneſs of the ſoil; and in theſe reſpects they differ in character from the rough iſlanders of Calamo and Lero, which are rugged countries. Its fertility, however, is checked by the empire of the Turks, to which it is ſubject; and the oppreſſive exactions to which its inhabitants are compelled to ſubmit: the ſhores abound with a great variety of fiſh. N. lat. 36° 40′. E. long. 26° 16′.

STAMPE, or Tempé, in *Commerce*, a ſmall copper coin in the Weſt India iſlands. In the Engliſh Leeward iſlands 1 ſtampe = $1\frac{1}{2}$ dog = $2\frac{1}{4}$*d.* Leeward currency, and 8 dogs or 4 ſtampes = 1 bit = 9*d.* of the ſame currency; the dollar in this currency being reckoned at 9*s.* In the French iſlands, the noir or dog is = 2 ſols 6 deniers = $1\frac{1}{2}$*d.* Leeward currency, and the tempé or ſtampe = 3 ſols 9 deniers = $2\frac{1}{4}$*d.* Leeward currency.

STAMPERS *and* Stamping, in *Coinage*. See Coin and Coinage.

STAMPING-Mill, or *Knocking-Mill*, an engine uſed in the tin-works to bruiſe the ore ſmall.

STAMPS, in *Metallurgy*, a ſort of large peſtles lifted up by water-wheels, and ſerving to beat to powder the ores, and refuſe of ores of metals.

STAMSLO, in *Geography*, a town of Hungary; 15 miles N.E. of Gros Wardein.

STAMWOOD, in *Agriculture*, a term applied to the roots of trees grubbed up. Any ſorts of root-wood are ſo termed in different ſituations and places.

STANCH, or Staunch, a name given by the country people of Northamptonſhire, and ſome other counties, to a ſpecies of foſſile called ſelenites, from its ſuppoſed virtue in ſtopping fluxes of blood. See Pachodecarhombis.

STANCHING *of Blood*, the ſtopping of blood in caſes of wounds in horſes or other animals. This is moſtly beſt performed by means of doſſels of lint and tow applied to the parts which are wounded.

STANCHIO, or Stancho, in *Geography*, an iſland in the Grecian Archipelago, anciently known by the name of *Cos* (which ſee), and by ſome modern geographers called "Lango." Of the ancient magnificence of this iſland no traces now remain. The modern town of Stancho is ſmall; its buildings are not particularly remarkable; though its ſituation on the ſea-ſhore is the ſame with that of the ancient city, and its environs are ſtill agreeable. It is ſurrounded by orchards of lemon and orange-trees, the flowers and fruit of which are equally regaling and refreſhing to its inhabitants, and afford them a valuable article of commerce. Cargoes of oranges and lemons are ſhipped here, and conveyed to different parts of Turkey, but principally to Smyrna and Conſtantinople. The harbour, which is defended by a caſtle, kept in bad order, though formerly ſafe and deep, can no longer receive any but ſmall veſſels: large ſhips remain without, in a road which has good holding-ground, but in winter it is open to the winds, and the ſwell from the north and weſt, and therefore avoided. The population of the town of Stancho is in a great meaſure compoſed of Turks: the Greeks occupy the remaining part of the iſland, but they are not numerous. The iſland, which is much longer than it is broad, is not very extenſive; but the beauty of its climate and of its ſoil, its fecundity, and its natural allurements, would render the paucity of its inhabitants extraordinary, if we did not recollect that it is under the immediate command of the Turks. Some writers have aſſerted that Stancho is an iſland ſubject to epidemical diſeaſes, and dangerous to be inhabited: but Sonnini ſays, that this aſſertion is ill-founded. Stancho retains the high character for mildneſs of climate, richneſs of ſoil, and ſalubriouſneſs of the air, given by the ancients to Cos. Some very high mountains command the ſouth part of the iſland: and navigators, deſirous of a ſhelter from the impetuous northerly winds, find a propitious retreat in that quarter in the little harbour of Safodino. The remainder of the iſland is a beautiful plain, abounding with various fruits, ſuch as oranges, lemons, figs, grapes, &c. which are delicious. The wine drawn from its grapes is delicate and agreeable. Its excellent paſtures formerly fed numerous flocks, that furniſhed wool, with which the inhabitants manufactured ſtuffs, held in high eſtimation for their fineneſs, and alſo for the brilliant colours with which they were dyed. But this kind of induſtry and its benefits are loſt. Its ſilk has alſo failed; though the climate is favourable to mulberry-trees, and the worm which feeds on them. Stancho is famous for a plane-tree, which covers the little public ſquare in which it is found with its antique and twiſting branches, and cools it with its impervious ſhade. Its thick branches are ſupported by pillars, or rather fragments of pillars, of marble and granite; and theſe pillars are the only ancient monuments which the iſland affords, if we except a few medals of little value. Under the ſhade of the plane-tree is a fountain, which ſupplies the Turks with water, and a coffee-houſe, which furniſhes a beverage that ſerves them in lieu of wine and every other fermented liquor. It is not improbable, that ten centuries have elapſed ſince this tree was planted. N. lat. 36° 46′. E. long. 26° 56′. The bay of Stanchio lies on the S.W. coaſt of Natolia, oppoſite to the iſland. N. lat. 36° 48′ to 37° 4′. E. long. 27° 14′ to 27° 44′.

STANCHIONS, in *Building*. See Punchion.

Stanchions, in a *Ship*, thoſe ſmall pillars of wood or iron which are uſed for various purpoſes; as to ſupport the decks, the quarter-rails, the nettings, the awnings, &c. The firſt of theſe are two ranges of ſmall columns fixed under the beams, throughout the ſhip's length between decks; one range being on the ſtarboard, and the other on the larboard ſide of the hatchways. They are chiefly intended to ſupport the weight of the artillery.

Stanchions *of the Nettings*, are either ſlender bars of iron, whoſe lower ends are fixed in iron ſockets at proper diſtances; or ſquare wooden pillars, let into the upper part of the ſhip's ſide. See Quarter-*Netting*.

STAND, Stableſtand. See Stableſtand.

Stand, in *Commerce*, a weight from two hundred and a half to three hundred of pitch.

Stand *of Arms*. See Arms.

Stand, *Bee*, in *Rural Economy*, is conſtructed in the form and manner of a ſlight ſhed, and made of good ſeaſoned wood, ſo framed, that the fore-part of the ſhed or ſtand may be about ſix or ſeven feet high, and the hind-part five or ſix. The top, and alſo the ends and back, muſt be well covered with ſtrong boards. The inſide ſhould, likewiſe, have a lining of very thin deal-boards, and be furniſhed with ſtrong ſhelves, ſo proportioned, as to ſuit the number of hives, boxes, or glaſſes, that are to be placed on them. And to the front, which ſhould be open, thin ſhades of wood ſhould be ſo formed and fixed up, that they may be raiſed or lowered, as may be neceſſary for the protection of the bees againſt either heat or moiſture. See Hive.

Stand, *Grain* or *Corn*, in *Agriculture*, the name of ſuch as are made of framed wood, ſtones, low walls, or other contrivances, and which are raiſed for placing grain upon, in making it into ſtacks.

The moſt ordinary mode of forming theſe ſtands is merely that of placing two or three pieces of large timber lengthways, and then putting ſmaller ones croſs-ways at the ends, filling up the middle parts with ſmaller pieces of wood or other materials. This is, however, a mode by no means to be generally employed, as it provides no ſecurity for the bottom of the ſtack. But in other caſes, a ſtrong framing of good timber is put upon poſts of wood, or what is better, of ſtones, about two feet high, provided with round caps of good flat ſtones, and on theſe the ſtacks reſt in a very ſolid and ſecure manner, and it affords a good and ſecure ſupport for the corn.

Theſe ſtack-ſtands are, however, much better when conſtructed wholly of ſtone, being built to the ſame height as in the former caſe, in a rather ſlanting manner outwards, and covered on the tops with copings of oak-planking or flat ſtones, which project over the edges ſeveral inches, and in that way prevent the depredations of rats and mice on the grain, as well as their lodging in the ſtacks. In both theſe modes, pieces of timber are placed as a frame in the middle, to ſupport the grain upon.

Further, in conſtructing theſe ſtands, the foundation ſhould be ſunk a conſiderable depth into the ground, and the bottoms be well laid, to prevent vermin getting to the grain of the ſtacks by working under them; and no ſort of ſubſtances ſhould ever be ſuffered to reſt againſt them, or the looſe corn to hang down during the time of building the ſtacks. It is obvious that the form of theſe ſtands muſt vary according to that in which the ſtacks are to be made, which is different in different diſtricts. The circular and oblong forms are the moſt uſual; but the long narrow ſhape is probably to be preferred, as it is ſaid, in the Agricultural Report of Northumberland, to keep the corn better, more dry, and freer from heating.

It has been remarked, that on brick or ſtone ſtands, ſtacks of the parallelogrammical form may be built to any ſize; but that for ſmall ſtacks, eſpecially where wood is employed, the octagonal form of ſtand ſhould rather be preferred to the circular one, as the copings may be cut with leſs waſte, and from ſmaller timber; and it is juſt as eaſy to build a circular ſtack on an octagonal ſtand as on a circular one. But that where ſtone can be eaſily procured, it is without doubt the moſt proper material for the bottoms ; and brick, when properly made for the purpoſe, anſwers very well, eſpecially if proper care be taken in the laying of it. Slate is alſo another material, where it can be had at a reaſonable expence, that may be a very good ſubſtance for this uſe. Likewiſe flag-ſtones would anſwer extremely well ; but neither ſlates nor flag-ſtones are neceſſary, if the foundations be laid ſufficiently deep to prevent the vermin burrowing under them. The celebrated Mr. Bakewell made uſe of ſtands of this kind with much advantage ; and other farmers, in the ſame diſtrict, probably employed them before his time.

Several different forms of ſtands of this ſort are employed on the farms of the duke of Bedford, at Woburn, and in other places. See Stack.

Stand, *Hay*, may be formed in ſomewhat the ſame manner as that for grain or corn, only it is ſeldom neceſſary to have it made of ſuch expenſive materials. A ſimple frame of wood is moſtly ſufficient, with proper bearers laid acroſs for the ſupport of the ſtack. See Stack and Stacking *of Hay*.

STANDARD, in *Commerce*, is a weight, meaſure, or coin, of acknowledged authority, by which others of the ſame denomination are ſized, compared, or adjuſted. (See Coin, Measure, and Weight.) We ſhall begin this important article with *Meaſures*, and conclude with *Coins*, including the new ſtandard weight for ſilver, of 1816.

When a ſtandard for linear meaſure is once eſtabliſhed, that for meaſures of capacity is eaſily deduced, by determining their cubic or ſolid contents ; and from the latter, ſtandard weights may be derived, as a veſſel of any certain dimenſions filled with pure water, at a given temperature, will always weigh the ſame in the ſame latitude.

It is, however, to be remarked, that this ſyſtematic mode of obtaining ſtandards has been ſeldom adopted, as they ſeem to have been generally eſtabliſhed at the will of individuals, or by the agreement of governments. Such are therefore called *arbitrary ſtandards*, to diſtinguiſh them from *invariable ſtandards from nature ;* that is, meaſures obtained from ſome unalterable property of nature ; as the dimenſions of the earth, the motions of the heavenly bodies, or the laws of gravitation. Theſe ſtandards have been anxiouſly ſought after by the firſt mathematicians of modern times ; but before their labours and reſearches are deſcribed, it will be proper to give an account of the paſt and preſent ſtate of arbitrary ſtandards, which are thoſe univerſally adopted, except in France.

The ſtandard meaſures of linear extenſion of all countries appear, from their names, to have been originally taken from ſome part of the human body, as the foot, the fathom, &c. But as ſuch muſt conſtantly vary with the different ſizes of men, ſtandards of ſome durable ſubſtance became neceſſary ; and it may be obſerved, that in country places where ſuch are not at hand, natural meaſures are ſtill occaſionally uſed, as the arm, the pace, &c. Hence ſome account of their proportions to each other cannot be unintereſting or foreign to our ſubject. The fathom is reckoned to equal the height or ſtature of a well-proportioned man : the pace is ſuppoſed to equal half of the ſtature, the cubit one-fourth, the foot one-ſixth, and the ſpan one-eighth. The breadth of the hand is reckoned one-third of the foot, that of the thumb one-twelfth, and of the finger one-eighteenth. Other proportions are occaſionally uſed, which, however, are not conſidered ſo regular as the above ; ſuch are the head, the arm, and the girth, &c. The head is particularly noticed by painters and ſtatuaries, who reckon the ſymmetry good when the whole height equals ſeven heads : but it has been made to equal more than ſeven and a half heads in ancient figures intended to repreſent dignity or ſtrength. The proportion, however, varies conſiderably among different races of men, and in different countries. The average of the European ſtature is from ſix to ſeven heads ; but that of the Kalmucks, Samoyedes, Laplanders, &c. is ſeldom more than five heads, and frequently leſs.

From ſuch an extraordinary variety may be traced the diverſity of ſtandard meaſures throughout the world. It has, however, been the endeavour of all regular governments to correct this inconvenience ; and hence eſtabliſhed ſtandards have been, from the earlieſt period of hiſtory, objects of peculiar care. They have been depoſited in the ſanctuary of the Jews, the temples of the heathens, and the churches of the primitive Chriſtians ; and diſtinguiſhed officers were always appointed to diſtribute copies of the ſame, to examine thoſe in uſe, and to correct or condemn ſuch as were found erroneous.

The Jews called their original ſtandard *ſcahac*, and thoſe copied from it, *meſſurah haddin*, or judged meaſures. We frequently read in ſcripture of "the weight of the ſanctuary," "the meaſure of the ſanctuary," and "the ſhekel of the ſanctuary." Numerous texts and precepts likewiſe occur in the ſacred volume to command uniformity.

The Greeks called their ſtandards *archetype*, *prototype*, and *metreon tropos ;* and it is ſaid, that at a very remote period they had but two ſtandards, namely, the *Pythic* and the *Olympic* meaſures. At Athens, fifteen officers were conſtantly employed for the regulation of their ſtandards. The ancient Romans likewiſe paid ſtrict attention to the ſame object, and are ſaid to have eſtabliſhed one ſtandard, called *menſura*, in every city throughout their vaſt dominions ; and each of thoſe meaſures was an accurate copy of the original, kept in the temple of Jupiter in the Capitol, which ſtandard was therefore called *capitolina*.

It is ſtated by ſeveral good authorities, that the Egyptians gave ſtandards at a very early period to the neighbouring countries of Aſia and Greece, from meaſurements made of an arc of the meridian. It is obſerved by Paucton, in his "Metrologie," that the baſe of their largeſt pyramid was made the principal ſtandard, which was the 500dth part of a degree of the meridian, previouſly meaſured for that purpoſe ; and Bailly, in his "Aſtronomie Ancienne," aſſerts that the Egyptian computation of the degree nearly correſponds with the modern meaſurement of the ſame arc. However this may be, there is little doubt but that uniformity of ſtandard meaſures was more ſtrictly eſtabliſhed among the ancients than among the moderns. The extenſive and arbitrary power poſſeſſed by many ancient ſovereigns muſt have greatly contributed to this. Even the Chriſtian emperors were very ſtrict in promoting uniformity, inſomuch that in the time of Charlemagne there was but one weight and one meaſure throughout his empire. In ſucceeding ages, however, a great diverſity was introduced in France by the abuſes of manorial rights and feudal tenures ; and to ſimilar cauſes may be aſcribed much of that variety which ſtill prevails in the different ſtates of Italy, Germany, Spain, and moſt other countries of Europe.

Theſe remarks naturally lead us to the conſideration of the ſtandards of our own country.

Standards of Engliſh Weights and Meaſures.—The ſtandards of Engliſh weights and meaſures are ſuppoſed to be chiefly of Saxon origin, but their early hiſtory is very imperfectly known.

Biſhop Fleetwood obſerves, in his "Chronicum Precioſum," that "there were good laws made on the ſtandards of weights and meaſures before the Conqueſt, by Edgar and Canute, but that they were never well obſerved." The ſame remark will indeed apply to many laws on the ſubject ſubſequent to that period.

Henry I. is ſaid to have paid much attention to the regulation of weights and meaſures, and to have adjuſted the Saxon *gyrd*, or girth, the modern yard, to the length of his arm. This ſtandard he depoſited in the Exchequer at Weſtminſter, where it is ſtill preſerved. As to the ſtandards of weights, they have undergone ſeveral alterations ſince that time. The troy weight, which is ſuppoſed to have taken its name from Troyes, in France, was introduced by the Normans, and contained at firſt 7680 grains, but was afterwards reduced to its preſent weight of 5760 grains. Before the reign of Henry VIII., the Tower or moneyer's pound was moſtly uſed for the precious metals, and was 15 dwt. leſs than the troy pound. About the ſame period the avoirdupois weight was eſtabliſhed for heavy goods, in the room of the old commercial weight, which latter is ſtill retained in Scotland under the name of the *Amſterdam weight;* and it is worthy of remark, that the aſſize of bread in England has been conſtantly fixed according to this ancient weight by the magiſtrates; the peck loaf newly baked being 16 lb. Amſterdam weight, which anſwers to 17 lb. 6 oz. avoirdupois.

Several ſtandards of weights and meaſures were anciently kept at Wincheſter, from whence our corn-buſhel derives its name; but in later times they have been chiefly kept in the Exchequer, at Guildhall, and at the Tower.

Preſent State of Engliſh Standards.—In the year 1758, the houſe of commons appointed a ſelect committee to enquire into the original ſtandards of weights and meaſures, and to report accordingly. They were aſſiſted in their reſearches by ſeveral eminent mathematicians and mechaniſts, who purſued the enquiry with great ſyſtem and ability. Their report, which is very elaborate, contains the reſults of numerous trials and compariſons made on the ſeveral ſtandards kept at the Exchequer and at Guildhall, which reſults were by no means ſatisfactory, particularly with regard to meaſures of capacity. Their labours, however, were not merely confined to compariſons and reſearches; they adjuſted with great accuracy two ſtandards, namely, the yard, and the pound troy, which are ſtill carefully preſerved, and conſidered of the firſt authority. The methods taken for preparing theſe ſtandards are detailed at conſiderable length in their report, and are well worthy of attention. On the queſtion, whether the troy or the avoirdupois pound ſhould be the ſtandard, they determined on the former, for the following reaſons. "Becauſe troy weight is beſt known to our law; that which hath been longeſt in uſe; that which is beſt known to the reſt of the world; that to which our learned countrymen have referred, in comparing ancient and modern weights; and the weight which hath been ſubdivided into the ſmalleſt parts. On the other hand, the avoirdupois weight is of doubtful authority; and though unfit to be made a ſtandard, yet the frequent uſe of it renders it neceſſary to aſcertain how many ounces, pennyweights, and grains troy, the pound avoirdupois ought to weigh."

The committee therefore obtained, with the utmoſt exactneſs, ſtandard weights of the ſeveral parts of the pound troy, which were made by Mr. Harris, the king's aſſay-maſter, with great ſkill, and proved by a very curious apparatus, contrived by Mr. Bird, the celebrated optician, which was adapted to five different beams, and which aſcertained the weights, from twelve ounces down to one grain incluſive, and that with ſo much correctneſs, as to diſcern any error in the pound to the 230,400dth of the weight, and to the 2000dth part of a ſingle grain. By this apparatus the ſeveral parts of the ſtandard pound were examined and adjuſted, in every progreſſive combination neceſſary to diſcover their proportions to each other; and upon all theſe trials the ſeveral weights appeared ſo exact, that, to uſe the words of the committee, "no greater degree of correctneſs could in the nature of things be expected."

A copy of this ſtandard pound was delivered to the houſe of commons, and another depoſited in the Mint, where it is ſtill preſerved, and alſo Mr. Bird's apparatus. With theſe ſome very accurate trials have been lately made by Mr. Bingley, the preſent aſſay-maſter. "One of thoſe trials deſerves particular notice, as tending to confirm the proportion between troy and avoirdupois weight, which has been differently ſtated in works of high authority, varying from 6998 to 7010 grains troy to the pound avoirdupois. It was, however, found by the trial above-mentioned, that the avoirdupois ſtandard pound kept in the Mint weighs exactly 7000 grains troy; and it was further aſcertained, that this pound of the Mint perfectly agrees with the bell ſtandard pound at Guildhall, and alſo with that, of 1588, kept at the Exchequer; and the agreement was the more curious, as the Mint ſtandard pound had always been kept carefully packed up in paper, while the other two were conſtantly in uſe, and expoſed to the atmoſphere." Univerſal Cambiſt, vol. i. p. xv.

The ſtandard yard of 1758 is ſtill carefully preſerved, and was compared with ſeveral others by profeſſor Pictet, in the year 1802. Theſe trials were made in the temperature of 62°, by means of the microſcopic beam-compaſs, conſtructed by Mr. Troughton, capable of aſcertaining differences to the 10,000dth part of an inch; and the following were the reſults, as compared with the ſtandard yard made by the ſame ingenious artiſt, and agreed upon by the Royal Society as the moſt accurate in its diviſions and the beſt medium of compariſon.

From the foregoing view it appears, that the preſent ſtandards of weights and linear meaſures are in a reſpectable ſtate of correctneſs; but it is to be obſerved, that meaſures of capacity are not ſo accurate, eſpecially in their ſubdiviſions; and the variations are greatly increaſed by local cuſtoms, particularly in corn meaſures; an evil which the power of parliament has been hitherto unable to correct, notwithſtanding the ſevere penalties which have been enacted at different periods to enforce uniformity. The committee of 1758 ſeemed to deſpair of ſucceſs in this reſpect, by the remark in their report, p. 460, "that the repeated endeavours of the legiſlature, ever ſince Magna Charta, to compel one weight and one meaſure throughout the realm, never having proved effectual, there ſeems little to be expected from reviving means which experience has ſhewn to be inadequate, and yet it was difficult to deviſe any thing entirely unattempted by former parliaments."

Since the above period, ſeveral publications have appeared on the ſubject of ſtandards, among which the communications

munications of ſir George Shuckburgh Evelyn, in the Philoſophical Tranſactions, deſerve particular notice, as very ſcientific and accurate. Plans too have been propoſed in parliament, and though not adopted, are well worthy of being recorded, as ſuch may prove uſeful on future occaſions.

In 1789, ſir John Riggs Miller moved for a committee of the houſe of commons "to inveſtigate and report on the beſt means of adopting an uniformity of weights and meaſures." He ſuggeſted the propriety of adopting the pendulum as the ſtandard of linear extenſion; but the ſubject was not reſumed the next ſeſſion. The plan, however, was ſtrongly recommended by a publication of the Rev. George Skene Keith, who propoſed the decimal ſyſtem, which was ſoon after eſtabliſhed in France.

In 1814, ſir George Clerk moved for a ſelect committee of the houſe of commons "to enquire into the original ſtandards of weights and meaſures, &c." And, in order to obtain information as to what were the beſt means of comparing linear meaſures with ſome invariable natural ſtandard, the committee examined profeſſor Playfair and Dr. W. Hyde Wollaſton. Their report on the occaſion contains much uſeful and important information; and a bill founded on it was brought into parliament. The plan was well received, and in the beginning of the preſent year, (1816,) the bill paſſed the houſe of commons without oppoſition, but was loſt on the ſecond reading in the houſe of lords.

The chief object of this bill was to aboliſh all the preſent meaſures of capacity, except coal meaſure, and to adopt one only in their ſtead. The propoſed ſtandard gallon was to be aſcertained by weight; that is, when filled with pure water at a temperature of 62°, it was to weigh 10 lb. avoirdupois, and this ſtandard was deduced from the weight of a cubic foot of pure water, which had been found to weigh, at the ſame temperature, 1000 ounces avoirdupois. Hence the propoſed gallon was to meaſure 276.48 cubic inches. It was likewiſe propoſed to make the avoirdupois, inſtead of troy weight, the ſtandard for regulating weights; and to adjuſt the long meaſures by the length of the pendulum. (Other particulars of this bill, as well as the report of the committee, may be ſeen in the Appendix to Kelly's Metrology.)

The committee, not ſeeming ſatisfied with the experiments hitherto made on the pendulum, referred the conſideration of the ſubject to the Royal Society, who have ordered a new meaſurement of it to be made. This operation is now in progreſs, under the direction of a committee, who have ſelected three members for the performance: namely, Dr. Young, Dr. Wollaſton, and Mr. Troughton. Since theſe experiments have commenced, the earl Stanhope has moved in the houſe of lords, that an addreſs ſhould be preſented to the Prince Regent to appoint a committee of ſcientific men, to be ſelected from the univerſities and mathematical inſtitutions, to determine on the beſt ſtandards for an improved ſyſtem of weights and meaſures.

From ſuch a co-operation much may be expected, and we hope to have an opportunity of ſtating important reſults in our article Weight. At preſent, we ſhall proceed to ſhew what has been hitherto effected in ſeeking invariable ſtandards from nature, and as the purpoſe of thoſe reſearches is of a popular nature, we ſhall endeavour to be as elementary and minute as the ſubject will admit.

Invariable Standards from Nature.—If arbitrary ſtandards could be preſerved uniform, they would anſwer all the uſeful purpoſes for which they are intended; but as all material ſubſtances are liable to decay, methods have been propoſed for obtaining ſtandards from ſome unalterable property of nature, by which loſt meaſures might be reſtored, or new ſyſtems eſtabliſhed: but it is remarkable that, in deducing ſtandards from nature, nature oppoſes many obſtacles difficult to be ſurmounted. Among the different methods that have been ſuggeſted, two only have been purſued with any degree of ſucceſs, namely, the length of a pendulum that vibrates ſeconds of mean time; and the length of an arc or portion of the meridian. If the earth had been a perfect ſphere, thoſe meaſures might be obtained without much difficulty; but it is a kind of oblate ſpheroid, having its equatorial diameter longer than its axis or polar diameter. Hence the gravity of bodies varies on its ſurface, in proportion to their diſtance from the centre of the earth; and, therefore, a pendulum muſt be longer at the poles than on the equator, in order to vibrate equal portions of time. From the ſpheroidical figure of the earth, too, the degrees of the meridian vary, increaſing in length, like the pendulum, from the equator to the pole. In order to aſcertain theſe variations, many calculations and meaſurements have been made by the greateſt mathematicians; and yet, with all their accumulated labours, up to the preſent time, the ſolutions are unſatisfactory. "It appears," ſays Laplace, in his Syſtème du Monde, "that the earth differs ſenſibly from an ellipſoid: there is alſo reaſon to believe that its two hemiſpheres are not equal on each ſide of the equator." Doubts are likewiſe entertained of the uniformity of gravitation in different longitudes, though in the ſame latitude; and alſo of the equality of degrees of the meridian in thoſe ſituations. The ratio, therefore, of any portion of the meridian to the whole circle is uncertain.

According to ſir Iſaac Newton's theory, the equatorial diameter is to the polar as 230 to 229; or, in other words, the earth's ellipticity is $\frac{1}{230}$. This computation was made on the hypotheſis, that the earth is an homogeneous ellipſoid; but on the ſuppoſition that it is heterogeneous, the ellipticity or oblateneſs is found to be leſs, as may be ſeen by the tables contained in this article.

The meaſurement of a degree of the meridian was attempted at a very remote period by the Egyptians, as already noticed; but from the rude and imperfect ſtate of the mechanical arts in ancient times, great doubts muſt be entertained of the accuracy of ſuch operations. With reſpect to the pendulum, it was not known to the ancients; but it has greatly engaged the attention of modern aſtronomers and mechaniſts, as well as the meaſurement of the meridian. For a particular account of both, ſee our articles Degree, Earth, and Pendulum.

Huygens was the firſt who propoſed the pendulum as the ſtandard for linear meaſure; that is, its length from the point of ſuſpenſion to the centre of oſcillation. The third part of this diſtance he termed the horary foot, which he recommended to be the univerſal ſtandard: but the variations of its length in different latitudes, as well as the great difficulty of obtaining the exact meaſurement, above ſtated, ſeemed to condemn this plan as wholly impracticable. The ſame ingenious philoſopher propoſed the method of obtaining the length of the pendulum by means of a rectangular cone; which when ſuſpended by its vertex, and made to vibrate, the centre of its baſe he demonſtrated to be the centre of oſcillation, and reciprocally, if ſuſpended by the centre of its baſe, its vertex would be the centre of oſcillation, ſuppoſing, in both caſes, that the length of the iſochronous ſimple pendulum was equal to the altitude of the cone, or the ſemidiameter of the baſe. He likewiſe ſuggeſted, as an invariable ſtandard of length, the ſpace that a heavy body would fall through in a ſecond of time; but this, like the pendulum, muſt vary in different latitudes, and is, moreover, affected by the reſiſtance of the atmoſphere. The operation is, in many other reſpects, very difficult to be performed with any degree of accuracy.

About the year 1778, the public attention was particularly excited and directed to the ſubject of ſtandards from nature, by the Society for the Encouragement of Arts, Manufactures, and Commerce, in London, who advertiſed a premium of 100 guineas, or a gold medal, as a reward to any perſon who would propoſe an improved means "for obtaining invariable ſtandards for weights and meaſures, communicable at all times, and to all nations." Among the candidates for this reward was Mr. Hatton, who propoſed the application of a moveable point of ſuſpenſion to one and the ſame pendulum, by which he intended to accompliſh the full effect of two pendulums; and the difference of their lengths was to be the required meaſure. Mr. Whitehurſt improved upon his plan by means of two pendulums, the vibrations of which were in a ratio of two to one. By this method it was generally admitted, that the difference between the rods of two pendulums, whoſe vibrations are known, is a datum from which may be derived an invariable ſtandard meaſure, as well as many other uſeful problems relative to gravitation, to falling bodies, and to the figure of the earth. By theſe experiments it was aſcertained, that the length of a ſeconds' pendulum in the latitude of London, vibrating in a circular arc of 3° 8′, is very nearly 39.119 inches, but performing the ſame motion in the arc of a cycloid, the reſult would be 39.136.

Experiments, which were ſuppoſed to be ſtill more accurate, were afterwards made by Mr. Graham; and a plan was propoſed to parliament, as before noticed, for adopting the pendulum as the ſtandard of length; but it was more warmly taken up in other countries. M. Talleyrand, then biſhop of Autun, and Mr. Jefferſon, the ſecretary of ſtate in America, turned their thoughts very earneſtly to the ſubject. Mr. Jefferſon propoſed, in the houſe of repreſentatives, that the length of a pendulum in lat. 38°, which he reckoned the medium of the United States, ſhould be adopted as a ſtandard on which to found a new ſyſtem of weights and meaſures, and his plans were approved, but never carried into effect.

It was firſt propoſed in France, that the length of the pendulum ſhould be made the ſtandard, taken in the latitude of Paris (48° 50′); but the latitude 45° was afterwards preferred, as moſt likely to be univerſally received, being the medium between the equator and the poles. A report to this effect was made to the National Aſſembly, in which it was agreed, that the meaſurement ſhould be entruſted to a committee of ſix members of the Academy of Sciences in Paris, and to ſix members of the Royal Society of London. But this plan was afterwards rejected by the academicians Lagrange, Laplace, Lalande, Borda, Monge, and Condorcet, who recommended a ſtandard from the meaſurement of an arc of the meridian. As this ſeems the moſt ſcientific operation, and important change that has ever been made in any ſyſtem of weights and meaſures, we ſhall give a full account of it here, extracted from their conſtitutional code.

Extract from the conſtitutional laws of the new ſyſtem of meaſures in France.

"By a decree of the 8th of May, 1790, ſanctioned the 22d of Auguſt, the conſtituent aſſembly deſiring that all France ſhould enjoy for ever the advantage that muſt reſult from an uniformity of weights and meaſures, commiſſioned the Academy of Sciences to determine the length of the pendulum, and thence to deduce an invariable ſtandard for all weights and meaſures.

"The length of the pendulum, at firſt, appeared proper for the baſis of the ſyſtem of meaſures, being eaſy to determine, and conſequently to verify, if it ſhould be neceſſary by any accidents happening to the ſtandards; but it was obſerved, that to take, as was propoſed, for the unit of meaſures, the length of the ſimple pendulum vibrating ſeconds, was to employ, in order to determine a meaſure of length, not only an heterogeneous element,—time, but alſo an arbitrary diviſion,—the 86,400dth part of the day. A meaſure of length was therefore preferred that did not depend on any other quantity; and it will be ſeen afterwards (*Précis des Experiences*, &c.) that obſervations of the pendulum can nevertheleſs be employed as a means of verifying, and even of finding that unit of meaſure, although they have not ſerved as the baſis of its determination. An unit of meaſure, taken on the earth even, has the advantage of being perfectly analogous to moſt of the meaſures that are likewiſe taken on the earth, as the diſtances between points of its ſurface, or the extent of portions of this ſame ſurface: it is, in fact, more natural to compare the diſtance of one place to another to the quadrant of one of the terreſtrial circles, than to the length of the pendulum. In ſhort, it was obſerved, that as the 10,000,000th part of the quarter of the meridian, or the metre, differed only from the pendulum vibrating ſeconds at Paris about ſix millimetres, both units would have led to reſults almoſt exactly ſimilar."

A ſecond decree of the ſame day commiſſions the Academy to appoint the moſt convenient ſcale of diviſion for weights and meaſures, and alſo for monies.

The decree of the 26th of March, 1791, ſanctioned on the 30th, to fix an unit of meaſure, natural and invariable, and which, in its determination, contains nothing arbitrary or peculiar to the ſituation of any people on earth, adopted, according to the advice of the Academy of the 19th of the ſame month, the dimenſions of the quadrant of the terreſtrial meridian as the baſis of the new ſyſtem of meaſures.

"The quadrant of the meridian ſhould be preferred to the quadrant of the equator, on account of the great difficulties that the neceſſary operations to determine this laſt element would have preſented, and their verification, if it were ever wiſhed to have recourſe to it. The regularity of this circle is not better aſcertained, than the ſimilitude or regularity of meridians. The ſize of the celeſtial arc anſwering to the portion of the equator that would have been meaſured, is leſs ſuſceptible of being determined with preciſion: in ſhort, every nation belongs to one of the meridians of the earth; one part only is placed under the equator."

The new ſyſtem of weights and meaſures, founded on the meaſure of the meridian of the earth, and on the decimal diviſion, was adopted by the law of the 1ſt of Auguſt 1793, under a nomenclature and on a baſis, both of which have ſince experienced changes.

"This nomenclature, modified by the law of the 30th Nivoſe an. 2, did not admit the decimal multiples *deca*, *hecto*, *kilo*, and *myria*, but only the ſub-multiples *deci* and *centi*. In order to make up for this, ſeveral denominations in each claſs of meaſures had been adopted. Thus, the *miliare* expreſſed 1000 metres; the *grade*, 100,000; the *cadil* correſponded with the litre, the *cade* to the kilolitre, the *gravet* to the gramme, the *grave* to the kilogramme, the *bar* to 1000 kilogrammes; and the words *decicadil*, *centricadil*, *decicade*, *centicade*, *decigravet*, *centigravet*, *decibar*, and *centibar*, expreſſed the tenth and hundredth parts of theſe different units. The name *are* was given to the meaſure at preſent called *hectare*: the *franc* ſhould be of the weight of 10 gravets, that is to ſay, double what it now is." According to this ſimple ſketch, it will be readily confeſſed that the nomenclature adopted by the law of 1795, is more methodical, more conformable to the principles of common numeration, and therefore more ſuſceptible of all applications of the decimal calculation.

Some laws applied alſo the decimal ſcale to the diviſion of the day and of the year, which did not require ſuch a change; they have been ſucceſſively repealed.

Extract from the law of the 18th Germinal, 1795, relative to weights and meaſures.

Art. II. There ſhall be but one ſtandard of weights and meaſures,—it ſhall be a rod of platina, on which the metre, the fundamental unit of the whole ſyſtem of meaſures, ſhall be traced.

The ſecond article of the law of the 19th Frimaire, 1800, acknowledges alſo the kilogramme for the ſtandard.

Art. V. Their nomenclature is definitively adopted as follows:

Metre, the meaſure of length, equal to the 10,000,000th part of the arc of the terreſtrial meridian, contained between the north pole and the equator.

Are, the meaſure of ſuperficies for land, equal to a ſquare of ten metres each ſide.

Stère, the meaſure particularly intended for fire-wood, and which ſhall be equal to the cubic metre.

Litre, the meaſure of capacity, both for liquids and dry goods, the contents of which ſhall be equal to the cubic metre.

Gramme, the abſolute weight of a volume of pure water, equal to the cube of the hundredth part of the metre, of the temperature of melted ice.

The unit of monies ſhall be called *franc*, to replace the name *livre*, uſed hitherto.

Art. VI. The tenth part of the metre ſhall be called *decimetre*, and its 100dth part *centimetre;* what ſhall be called *decametre* is a meaſure equal to 10 metres, which ſupplies a convenient meaſure for ſurveying. *Hectometre* ſhall ſignify the length of 100 metres. *Kilometre* and *myriametre* ſhall be lengths of 1000 and 10,000 metres, and ſhall deſignate principally itinerary diſtances.

Art. VII. The denominations of the meaſures of other kinds ſhall be determined according to the ſame principles as thoſe of the preceding article.

Thus, *decilitre* ſhall be a meaſure of capacity ten times ſmaller than the *litre; centigramme* ſhall be the 100dth part of the weight of a gramme.

Decalitre ſhall likewiſe be uſed to deſignate a meaſure containing 10 litres; *hectolitre* for a meaſure equal to 100 litres; a *kilogramme* ſhall be a weight of 1000 grammes.

In a ſimilar manner the names of all other meaſures ſhall be compoſed.

For a compariſon of the French and Engliſh weights and meaſures, ſee our articles MEASURE and WEIGHT.

Preſent State of Standards of Weights and Meaſures in France,—The ſucceſs of the metrical ſyſtem adopted in France is a ſubject of intereſting and important inquiry. The plan was originally conſidered ſo excellent, that hopes were entertained of other nations following the example. This expectation, however, has not been realized, nor has that beautiful and ſcientific theory been found unexceptionable in practice. On the contrary, it met with ſuch oppoſition on account of the Greek and Latin terms, and the decimal diviſions, that in 1801 the government allowed the people to uſe, for a limited time, their ancient vocabulary of names, applying them to the new ſtandards, which are ſtill retained. And in 1812, a further conceſſion was made, by the imperial government, to the prejudices and habits of the people. They were allowed to continue the ancient vocabulary applied to the new ſtandards, with the word *uſuel* added to each: thus, two metres are the *toiſe uſuelle;* half a kilogramme, the *livre uſuelle*, &c.: and theſe units are not divided decimally, but into halves, quarters, and eighths: the long meaſures are alſo divided duodecimally.

Beſides the binary diviſions of weights, the *livre uſuelle* is divided into ounces, gros, and grains, like the ancient livre, *poids de marc*. Hence, the new ounce and its diviſions depart ſo widely from the gramme, that the proportion cannot be aſcertained without a troubleſome calculation.

Thus, after more than twenty years of troubleſome experiment and trial of the metrical ſyſtem, the only advantage that has been gained is that of eſtabliſhing one common ſtandard, the *metre;* but uniformity might as well have been obtained by making their ancient toiſe, (ſo univerſally known,) their ſtandard. The chief recommendation of the metre, as ſtated in the foregoing decree, as well as by the authors on the metrical ſyſtem, Brillat, Briſſon, and Tarbé, is, that ſhould it be ever altered or loſt, it may be eaſily reſtored, not by a ſecond meaſurement of the meridian, but by a compariſon with the pendulum. Thus they allow the pendulum to be the regulator of linear meaſure as well as of time, and, in ſhort, the ultimate criterion, and of courſe the principal ſtandard.

The following tables ſhew at one view the labours of the greateſt mathematicians and philoſophers to determine the figure of the earth, and thence to deduce ſtandard meaſures. But it may be proper firſt to premiſe, in addition to our account of experiments on the pendulum by the Engliſh and French aſtronomers, what thoſe of Spain have recently done in different parts of the globe, in purſuit of the ſame important object.

About the year 1789, the Spaniſh government ſent out an expedition of two frigates, the Deſcubierta and the Atrevida, under the command of Alexander Malaſpina, in order to make experiments with the pendulum in different parts of the world, and particularly with a view to aſcertain if the ſouthern hemiſphere differed from the northern, as was ſuppoſed, and indeed warranted, by the few meaſurements antecedently made on the ſouth ſide of the equator by La Caille and Bouguer.

The new experiments were made with a deal rod pendulum, and other neceſſary apparatus, under the direction and management of M. Ciſcar, who appears to have been well qualified for the undertaking. The particulars of his important labours are detailed by M. Mathieu, in the "Connoiſſance des Tems" of the preſent year (1816), who ſtates that M. Ciſcar made ſixteen experiments, from N. lat. $59\frac{1}{2}°$ to S. lat. $51\frac{1}{2}°$, and in very different longitudes; and compared them with the theory which Laplace eſtabliſhed in his "Mecanique Celeſte," on fifteen meaſurements of the pendulum, which led, by one method of calculation to make the earth's ellipticity $\frac{1}{321}$, and by another $\frac{1}{336}$. The reſults deduced from M. Ciſcar's experiments do not determine which is correct, but they tend to ſhew that the two hemiſpheres are nearly alike, as may be ſeen by the following table of ellipticities.

As to the lengths of the pendulum, they do not differ materially from thoſe already computed, making allowance for its being lengthened, in order to make the ſame number of vibrations in a vacuum as it did in the air. The calculations given of theſe alterations, according to the variable ſtate of the atmoſphere, are very curious, and well worthy the attention of philoſophers engaged in experiments on the pendulum.

We have purſued this article to conſiderable length, as well on account of its general importance, as its peculiar intereſt at the preſent time, when plans are ſet on foot for eſtabliſhing new ſtandards, and improving the Britiſh ſyſtem of weights and meaſures.

From the foregoing view of the ſubject it appears, that, however profound and accurate the labours of the learned have been in ſearch of invariable ſtandards from nature, weights and meaſures have hitherto derived but little practical advantage from their reſearches, except indeed what has been effected in France; and the utility of the alterations there is queſtionable, when balanced againſt the great inconvenience that has been experienced, and which is likely long to continue.

The chief uſe of ſtandards from nature is to reſtore eſtabliſhed meaſures, ſhould they be ever loſt; a ſuppoſition highly improbable, and of which there are few examples. In ſhort, ſtandards from nature can be only known by compariſon with a ſcale of eſtabliſhed arbitrary meaſures. The reſearches of the learned, however, ſhould be encouraged, as they may likewiſe lead to other uſeful and important diſcoveries in arts and ſciences.

The plan of aſſimilating the ſtandards of different nations has been at all times a favourite ſubject with philoſophers and ſtateſmen. Such was the benevolent but Utopian wiſh of Budeus, an eminent author of the twelfth century, who thus expreſſes himſelf in his work, entitled "De Re Nummaria."

> "Una fides, pondus, menſura, moneta ſit una,
> Et ſtatus illæſus totius orbis erit."

> "One faith, one weight, one meaſure, and one coin,
> Would ſoon the jarring world in friendſhip join."

"Experience, indeed, ſhews (ſays a late writer on Metrology), that plans for aſſimilating the ſtandards of different countries, are as impracticable and viſionary as propoſals for eſtabliſhing an univerſal language. Hiſtory likewiſe ſhews, that while governments change with great facility their money ſyſtems, their conſtitution, and even their religion, weights and meaſures ſeem immoveable. They are indeed ſo mixed, and, as it were, matted with every concern of property, that they cannot be eſſentially altered without violence and confuſion; nor are thoſe evils of a temporary nature. The habits, cuſtoms, and prejudices of the multitude are not to be ſpeedily changed. It was computed in France, that in three generations their metrical ſyſtem would be fully eſtabliſhed; but now it ſeems to require more. In England, the conſtant vigilance of the legiſlature for 500 years has been employed in correcting abuſes rather than in improving the ſyſtem. In ſhort it appears, that nothing has a greater tendency to grow worſe, or more obſtinately reſiſts improvement, than weights and meaſures."

Standard of Bullion and Coins.—The ſtandard for bullion is a certain proportion fixed by law between the weight of pure gold or ſilver in any quantity, and the weight of alloy, which proportion is called the *fineneſs*. Thus, the ſtandard fineneſs of gold coins in England is 22 carats, or $\frac{22}{24} = \frac{11}{12}$; and the ſtandard fineneſs of ſilver coins is 11 oz. 2 dwt., or $\frac{37}{40}$. See our articles ASSAY, BULLION, and COIN.

Wrought gold, however, has two legal ſtandards; the one 22 carats, as above, and the other 18 carats; the latter began in 1798, and is chiefly uſed for watch-caſes and rings.

Wrought ſilver has likewiſe two legal ſtandards; the one 11 oz. 2 dwt., as above, and the other 8 dwt. better; that is, 11 oz. 10 dwt. The latter, which is called new ſterling, is of ancient ſtanding, but ſeldom uſed.

Standard of Coins.—Beſides the legal fineneſs for coins, there is alſo a ſtandard weight fixed by law. Thus in England, a pound troy of ſtandard gold is coined into 44½ guineas, and of ſtandard ſilver into 62*s*. A law, however, has been recently enacted (June 1816), by which the ſtandard weight of ſilver is altered, but the fineneſs both of this metal and of gold remains unchanged.

The new ſtandard Weight of Engliſh ſilver coin is, that one pound troy of ſtandard fineneſs ſhall be coined into 66*s*. Thus the weight of the new ſhilling is to be 3 dwt. $13\frac{3}{11}$gr. and the other new ſilver coins in proportion.

No alteration is to take place in the gold coins; but gold pounds are to be coined in proportion to the guinea. Each will therefore be $\frac{20}{21}$ of a guinea, and muſt weigh 5 dwt. $3\frac{171}{623}$ gr. of ſtandard gold, and 113 gr. of pure gold, without any allowance for remedy. But according to the regulation which allows a guinea of 5 dwt. 8 gr. to be a legal tender, the gold pound weighing 5 dwt. $1\frac{39}{21}$ gr. will be alſo legal.

By the new law of 1816, gold is declared to be the ſtandard of value, or the meaſure of property, by which the par of exchange, and the value of ſilver and all other commodities, ſhould be eſtimated.

It has been long a queſtion of doubt, whether gold or ſilver ſhould be the ſtandard of value. Locke and other authorities ſtate it to be ſilver; but lord Liverpool, in his "Letter to the King on the Coins of the Realm," obſerves, that "coins, which are the principal meaſures of property, ſhould be compoſed of one metal only, and that this ſhould be gold."

By a law of 1799, the queſtion was ſettled with reſpect to large payments, as it was then declared that ſilver ſhould not be a legal tender for any ſum above 25*l.*; but by the law of 1816, gold is the only legal tender that can be made for any ſum exceeding 42 ſhillings.

Standarding Bullion and Coins.—The precious metals in England, whether in bullion or foreign coins, are generally bought and ſold at ſo much *per* ounce ſtandard, which is calculated from the aſſay-maſter's report of weight and fineneſs.

The following are the characters generally uſed in thoſe reports.

j	is	1	dwt. or oz.
ij	—	2	ditto.
𝒬	—	5	ditto.
ℭ	—	10	ditto.
ℭ𝒬	—	15	ditto.
ℭ𝒬iij	—	18	ditto.
ℭ/ℭ	—	19	ditto.
ob.	(obolus)	½	ditto.

Rules for ſtandarding Bullion and Coins.—The common method of finding the value of ſmall quantities of gold and ſilver is by allowing, from the aſſay-maſter's report, at the rate of 4*s. per* carat, B. or W., in every ounce weight of gold; and at the rate of 6*d. per* ounce, B. or W., in every ounce weight of ſilver. But when ſilver is more than 10 dwt. worſe, an allowance of 2*d. per* ounce muſt be made for refining.

The following are the ſcales of allowance.

Scale for Gold.	*Scale for Silver.*
1 car. (4*s.*	1 oz. (6*d.*
1 gr. (1*s.*	15 dwt. (4½*d.*
½ gr. (6*d.*	10 dwt. (3*d.*
¼ gr. (3*d.*	5 dwt. (1½*d.*
	2½ dwt. (¾*d.*

Thus, to find the value of 2 oz. of gold B. 1 car. 1 gr. at 4*l. per* oz. To 8*l.* (for 2 oz.) add 10*s.* for better, which gives the value 8*l.* 10*s.* And to find the value of 12 oz. of ſilver, W. 10 dwt. at 5*s.* 6*d. per* oz. From 3*l.* 6*s.* (for 12 oz.) ſubtract 3*s.* for worſe, which gives the value 3*l.* 3*s.*

Rules for ſtandarding Gold.—As 22 carats are to the aſſay or report of fineneſs, ſo is the groſs weight to the quantity that is to be added or ſubtracted from this groſs weight, according as the report is *better* or *worſe.* If better, the additional quantity is called (by the trade) *betterneſs,* and if worſe, the ſubtractional quantity is called *worſeneſs.*

Example.—How much ſtandard gold is there in an ingot of the following report, B. 1 car. 3½ gr. weight, 67 oz. 15 dwt. 8 gr.?

```
                   oz. dwt. gr.
As 22  :  1 3½  ::  67  15  8
    4     4              20
   ——    ——         ————
   88     7           1355
    4     4             24
  ———    ——        —————                  gr.      oz. dwt. gr.
  352    30        32528 × 30 ÷ 352 = 2772  =   5  15  12

              oz.  dwt.  gr.
         To   67   15     8  groſs weight
        Add    5   15    12  betterneſs.
              ——————————————
              73   10    20  ſtandard.
              ——————————————
```

The following method for ſtandarding gold may be generally uſed with advantage.

```
                oz. dwt. gr.
                67  15   8  groſs weight, B. or W. 1 car. 3½ gr.
2 gr  =  ½      33  17  16
1     =  ½      16  18  20
½     =  ½       8   9  10
             ——————————————
             2)127   1   6 ⎫
             ——————————————⎬ divided by 22.
            11)63   10  15 ⎭
             ——————————————
                 5  15  12  betterneſs or worſeneſs, as above.
               ————————————
```

Rules for ſtandarding Silver.—As 11 oz. 2 dwt. are to the aſſay, ſo is the groſs weight to the quantity that is to be added or ſubtracted.

Example.—In 287 oz. of ſilver, W. 12½ dwt., how much ſtandard?

```
As 11   2 : 12½  ::  287
    20                20
   ———               ————
   222               2840
                        12½
                   ——————— dwt. gr.    oz. dwt. gr.
             222)71750(323   4   =  16   3   4

                   oz. dwt. gr.
      From         287   0   0  groſs weight
      Subtract      16   3   4  worſeneſs.
                   ————————————
                   270  16  20  ſtandard.
                   ————————————
```

From the laſt example, the reaſon of the following rule for ſtandarding ſilver is obvious, *viz.*

Multiply half the weight in ounces by the aſſay in pennyweights, and divide the product by 111, the quotient will be the betterneſs or worſeneſs in ounces.

Example.—How much ſtandard ſilver in 160 ounces of B. 18½ dwt.?

```
Half weight 80
            18½
         ——————
   111)1480(13 oz. 6 dwt. 16 gr.
       111
       ———                 oz. dwt. gr.
        370        To      160  0   0  groſs
        333        Add      13  6  16  betterneſs.
        ———                ——————————
         37                173  6  16  ſtandard.
          20 &c.           ——————————
         ——
```

It ſhould be obſerved, that there are tables conſtructed, and ſometimes uſed, for ſtandarding gold and ſilver, as may be ſeen in Poſtlethwayt's Dictionary of Commerce, vol. i. p. 388—398. But from the ſimplicity and conciſeneſs of the foregoing examples, it is manifeſt that ſuch tables cannot much ſhorten the operation, though they may ſerve to check or prove the calculation. Univerſal Cambiſt, vol. ii. p. 193.

Standard, in *Botany* and *Vegetable Phyſiology*, *Vexillum*, is the ſolitary ſuperior petal of papilionaceous flowers, generally of a larger ſize, and more conſpicuous colour, than the other petals. See Papilionaceous.

Standard, in *War*, a ſort of banner or flags borne as a ſignal for joining together of the ſeveral troops belonging to the ſame body. See FLAG, &c

The ſtandards were originally large flags, fixed on the tops of towers or other elevated places; and from their being ſtationary, were called ſtandards: though this term was afterwards given to moveable enſigns, as at preſent to thoſe borne by the cavalry.

Du-Cange derives the word from *ſtandarum* or *ſtantarum*, *ſtandardum* or *ſtandale*, words uſed, in the corrupt Latin, to ſignify the principal flag of an army. Menage derives it from the German, *ſtander*, or the Engliſh, *ſtand*.

The ſtandard is uſually a piece of ſilk, a foot and a half ſquare, on which are embroidered the arms, device, or cypher of the prince, or of the colonel. It is fixed on a lance, eight or nine feet long, and is carried in the centre of the firſt rank of a ſquadron of horſe by the cornet.

The ſtandard is uſed for any martial enſign of horſe; but more particularly for that of the general; or the royal ſtandard. Thoſe borne by the foot are rather called colours.

The ancient kings of France bore St. Martin's hood for their ſtandard. The Turks preſerve a green ſtandard, borne by Mahomet, with a great deal of devotion, as believing it to have been brought down by the angel Gabriel. Every time it is diſplayed, all who profeſs the Mahometan faith are obliged to take arms; thoſe who refuſe are to be deemed as infidels.

STANDARD-*Guard*. See GUARD.

STANDARDS, for the *Roman*, ſee SIGNA.

STANDARD, *Royal*, in *Sea Language*, is a flag in which the imperial enſigns of Great Britain, and the arms of France and Ireland, together with the armorial bearings of Hanover, are united and quartered. This is never hoiſted unleſs when the ſovereign is aboard, and then it is diſplayed at the main-top-maſt-head.

STANDARDS, in *Ship-Building*, large knees of oak or iron, fayed on the deck and againſt the ſide. The arm upon the deck ſtands upon a ſole, and is bolted through the beams, and clenched underneath; and the other arm through the ſhip's ſide. There is alſo a ſtandard fayed on the gun-deck, againſt the apron forward, and another againſt the tranſoms abaft; alſo one againſt each riding-bitt, and one in head upon the knee, when the piece againſt the ſtem does not run high enough for the hole of the main-ſtay collar. Standards are alſo large poles, ſet up endways, about ten feet aſunder, round the edges of ſlips, to which the ſpars are hung to ſupport the ſtaging. They have cleats nailed up their foremoſt and after ſides, at about two feet diſtance.

STANDARD *Trees*, in *Planting*, are all ſuch as ſtand ſingly, with an upright ſtem, without being trained to any wall or other ſupport. In *Gardening*, they are moſtly diſtinguiſhed into three ſorts; as *full ſtandards*, *half ſtandards*, and *dwarf ſtandards*, from their being occaſionally trained in all theſe ways; but foreſt and tall ornamental trees rarely in any other than full ſtandards; though in the ſhrub tribe they are occaſionally formed into both half and dwarf ſtandards, according to their natural growths.

Full ſtandards are ſuch trees as are trained with tall, ſtraight, clean ſtems, ſix or ſeven feet high, or more, then ſuffered to branch out at that height all around, to form a head, as in common ſtandard apple and pear-trees, ſome foreſt-trees, &c. Theſe ſhould be trained accordingly in their minor growth, by trimming off all the lower lateral branches gradually, as the ſtem advances in height; ſuffering the leader always to remain entire, eſpecially in all foreſt-trees; or, if it ſhould happen to fork, taking off the worſt, and leaving the ſtraighteſt ſhoot to run up, to continue the prolongation of the ſtem to the height above-mentioned. In fruit-trees, the ſtem is often cut or topped at the height of ſix or ſeven feet, to force out a ſet of laterals in that part, ſo as to form a regular ſpreading head of a moderate height, for the greater convenience of gathering the fruit; but for all kinds of foreſt-tree ſtandards, the tops ſhould never be reduced, but the leaders be permitted to remain entire to run up in height; as the beauty and worth of ſuch trees conſiſt in their lofty growth.

Moſt ſorts of fruit-trees may be trained for full ſtandards, except vines; though ſome of them will not ripen their fruit effectually in this way, as peaches, nectarines, and figs: but, on the other hand, all ſorts of apples, pears, plums, and cherries, ripen their fruit freely on ſtandards of this kind.

And all ſorts of fruit-trees for this purpoſe are moſtly raiſed by grafting, &c. on the freeſt ſtrong-ſhooting ſtocks, and trained with ſtraight clean ſtems full five or ſix feet high, as above, either the ſtock trained up to that height, and then grafted or budded, the graft or bud branching out forming the head; or the ſtock grafted near the ground, and the firſt ſhoot from the graft or bud trained up for a ſtem to the proper height, then ſuffered to ſend forth branches: in either method, it is next to be conſidered whether it be intended the tree ſhall form a ſpreading open head, or aſſume a more erect and aſpiring growth: in the former caſe, if the leading ſhoot of the graft or bud be topped at ſix or ſeven feet from the ground, it will force out lateral ſhoots at that height, and commence a ſpreading head, open in the middle, ſuffering, however, the whole afterwards to take their own growth; and in the latter, by permitting the leading ſhoot to remain entire, it will aſpire in height, and the whole head will aſſume a more upright and lofty growth: in both methods the heads will afterwards naturally branch out abundantly, and furniſh themſelves ſufficiently with bearing wood, producing fruit, in ſome ſorts, in two or three years from the grafting and budding, as in cherries, apples, &c. but pears are ſometimes four, five, or ſix years before they bear. See GRAFTING.

It is expedient to train moſt of the principal hardy fruit-trees as full ſtandards, that, when planted in continued rows, either in gardens or orchards, by having tall ſtems, they may admit the influence of the ſun and air more freely to the heads, and permit the obtaining crops of eſculent plants, graſs, &c. from the ground under them, over which their ſpreading branches extend.

In reſpect to the management of full ſtandard fruit-trees, little is required, after the firſt training, to form the ſtem to the proper height, and the firſt ſhoots are advanced at top, to give the head its firſt formation; being allowed to advance nearly in their natural order, except reducing any very irregular growths, permitting the whole to ſhoot in length, and branch laterally in their own way; by which they naturally form fruit-ſpurs along their ſides upwards for bearing. The irregular branches muſt, however, be removed, and the heads kept properly thinned, as well as the ſuckers rubbed off from the ſtems or other parts, and the dead wood be wholly taken away. See PRUNING.

Standard fruit-trees with high ſtems are ſometimes planted againſt walls, and trained as wall-trees: this is practiſed for high walls, ſo as immediately to cover the upper parts of them, whilſt dwarfs and half ſtandards cover the bottom and middle parts, and thus every part of the wall is fully occupied at once: but in theſe caſes the dwarf-trees are to remain, the others being wholly deſtroyed after a time. See Wall-*Trees*.

Theſe ſorts of high ſtandards are likewiſe occaſionally placed againſt the ends of buildings; ſome choice ſorts of pears in particular: alſo apricots in a ſoutherly aſpect, and other fruit-trees of the ſame kind.

Half ſtandards are trained with ſtems only three or four feet high, and then ſuffered to branch out to form heads. It is a method of training practiſed for many ſorts of fruit-trees, both as detached ſtandards for variety, and the convenience of gathering the fruit, and with fanned ſpreading heads, as wall-trees for high walls, in order to cover certain parts of them.

The method of raiſing theſe is nearly the ſame as for full ſtandards, only they are grafted or budded upon lower ſtocks, training them with upright ſingle ſtems only three or four feet high, by the ſtocks on which they are grafted being trained up to that height for a ſtem; or by being grafted or budded low in the ſtock, and the firſt main ſhoot of the graft, &c. led up for a ſtem, and topped at that height to force out branches to form the head; ſuffering the heads, in thoſe deſigned as detached ſtandards, to branch out all around, and run up to a full ſpread, nearly according to their natural mode of growth, except juſt reforming any ill-growing branch, as ſhortening the branches ſhould be ſparingly practiſed, as it would force out numerous uſeleſs ſhoots, and prevent the formation of bearing wood, eſpecially in the apple, pear, plum, and cherry kinds.

But when half ſtandards are intended for walls, they ſhould have the head trained in a ſomewhat fanned manner, to ſpread to the wall like a common wall-tree. And when it is neceſſary to have them to form heads of as moderate growth as poſſible, eſpecially in the detached half ſtandards for ſmall compartments, they ſhould be grafted or budded upon the more dwarfiſh ſort of ſtocks, as apples upon codlins, and pears upon quinces, &c.; in which caſe the heads will always ſhoot moderately, and never ramble wide or grow high. See Stocks.

But though a few of this ſort of trees may be eligible as detached half ſtandards for variety, they are not proper for the open quarters of the garden; as the branches coming out low may impede the growth of under-crops. A few might, however, be thinly ranged and planted along the ſides or boundary parts of large wide compartments, particularly of thoſe ſorts that are wrought on dwarf-ſtocks, which commonly branch more moderately, and in a leſs ſpreading manner: as a good portion of the common codlin-kind, which naturally ſhoot moderately, and are good bearers; the heads in which being, for the moſt part, ſuffered to run in their natural way of growth, except juſt a little occaſional regulation and pruning of their branches, as ſuggeſted for full ſtandards. For walls, however, that are eight or nine feet high, they are proper to plant between the dwarfs or principal reſidents, to cover the middle, or upper half of the wall, whilſt the dwarfs occupy the lower ſpace. See Wall-*Trees*.

Half-ſtandard cherries, apricots. &c. are alſo proper to plant in forcing-frames, to produce early fruit. See Forcing-*Frames*.

The after-management of detached trees of this ſort, in reſpect to pruning, is nearly the ſame as that of the full ſtandards; as, after having ſhot out at top to form the head, they ſhould be permitted to branch both in length and laterally nearly in their own way, except juſt pruning to order any conſiderable irregularity, crowding branches in the middle, or long ramblers, and detaching all ſuckers from the root, ſtem, and head, and cutting out caſual dead wood; and thus the regular branches remaining, at length will emit fruit-ſpurs abundantly in every part for bearing. And the half ſtandards againſt walls are to be pruned and managed as other wall-trees, each according to its nature and habits of growth.

Foreſt-trees, and the taller ſorts of the ornamental tree kinds, are ſeldom or ever trained as half ſtandards, but moſtly ſuffered to run up in height to their full growths, unleſs ſome particular ſort may be required to have the form of a buſhy half ſtandard for ſome ſpecial uſe or purpoſe.

Several plants of the ſhrub kind, in their natural growth, aſſume ſomething of the appearance of half ſtandards, though, in moſt inſtances, they are branchy to the bottom, or riſe with different ſtems; but they might be moſtly trained with a ſingle clear ſtem to the height of three or four feet, and be then ſuffered to branch out into full heads, like half ſtandards.

Dwarf Standards.—Theſe are trained with low ſtems, only one or two feet high, and then topped, to force out branches to form the head. There are ſeveral ſorts of choice fruit-trees which are trained as dwarf ſtandards, with ſtems not more than one foot high, branching out at that height, forming proportionably low heads; they being occaſionally planted round the borders of the kitchen or pleaſure-garden, &c. inſtead of eſpaliers, and the heads either kept down low by cloſe pruning, or ſuffered to branch upward nearly in their natural growth. Theſe are raiſed by grafting, &c. upon the moſt dwarfiſh ſtocks, ſuch as apples on codlin or paradiſe-ſtocks, and pears on quinces, &c. in order to dwarf them as much as poſſible in their growth; and as they ſhoot in height, each year's ſhoots either pruned ſhort, to keep the head down, and confine it within a ſmall compaſs; or the branches permitted to ſhoot in length, except juſt reducing caſual ramblers and diſorderly growers. But by too ſevere pruning, too many uſeleſs ſhoots are forced out annually, and a ſufficiency of bearing wood ſeldom produced, ſo that it rarely anſwers well, while by ſlight pruning, the trees moſtly ſhoot more moderately, and ſooner form themſelves into plentiful bearers in better perfection. Theſe kinds of dwarf ſtandards are not ſo generally introduced now, ſince eſpalier fruit-trees have been brought to a proper degree of perfection in training and bearing. They might, however, be ſparingly admitted, where neceſſary, in their different ſorts, under proper moderate pruning, according to their nature.

Some have dwarf ſtandard fruit-trees in pots, for the purpoſe of forcing in hot-houſes, forcing-frames, hot-beds, &c. particularly early May and May-duke cherries, plums, peaches, nectarines, apricots, figs, vines, gooſeberries, currants, &c. which being placed as above, in January, or early in February, often ripen a few fruit very early in tolerable perfection, ſome of which might be brought to table growing on the trees in the pots. Dwarf ſtandard fruit-trees are alſo proper to plant out fully in the borders, in forcing-frames and houſes. See Forcing-*Frame* and Dwarf-*Trees*.

Alſo the different varieties of currants and gooſeberries may be trained with a ſingle ſtem a foot or more high, and then permitted to branch out into a regular head, keeping the internal part always tolerably open, and the branches moderately thin; and ſhortening them but ſparingly, particularly the gooſeberry, by which dwarf ſhrubby plants are formed, and which become very productive.

There are different ſhrubby plants of the evergreen and flowering upright one-ſtemmed kinds, too, which may be trained as dwarf ſtandards, though the greateſt number of plants of the ſhrubby ſort are the moſt ornamental when they riſe in a buſhy manner, with many ſtems from the bottom. Theſe plants, when neceſſary, are to be trained with one ſtem, which is readily accompliſhed by retrenching and removing the ſuperfluous parts, and trimming away all low ſtraggling branches, ſo as to form a clear ſingle ſtem for a ſmall ſpace at the bottom parts, as the nature of their growth may require, then ſuffering them to branch out into full heads.

Some of the low ſhrubs of the above ſorts are ſuppoſed by ſome to appear to the beſt advantage when trained in this manner.

General Culture.—In regard to the management of ſtandard trees of the fruit kind, when they are planted out in an irregular manner throughout the whole garden ground, which is never, or very rarely, an eligible practice, little is to be done in the way of ſuiting them to the nature and cultivation of the ground or ſoil, as they muſt neceſſarily give way in theſe reſpects to the ſorts of crops which are to be raiſed upon the different quarters or parts of the ground. Mr. Loudon has, however, ſuggeſted, that the beſt way of employing ſtandard fruit-trees and ſhrubs in gardens, or all which are unfaſtened, is either in rows, in the manner in which gooſeberry plants or buſhes are uſually ſet along the ſides of the beds or borders, in particular quarters of the ground by themſelves; or in orchard-grounds. Standard trees of theſe kinds, for the borders in kitchen-gardens, ſhould always, it is ſaid, be kept low, in order that they may ſhade the crops on the different ſides as little as poſſible. But it is thought to be perhaps the beſt way to have ſeparate diſtinct quarters or parts for ſtandards of theſe kinds; to have thoſe of the apple and pear ſorts grafted on paradiſe or quince-ſtocks, by which means they come ſooner into a fruiting ſtate; and by the time thoſe in the orchards or on the walls are in a full bearing condition, ſuch quarters are fit to be thrown out: and, if neceſſary, other quarters might be planted to ſucceed them. In this manner, when a new garden was wanted to be made, a tolerable ſupply of fruit might be had every year after the third; it being well known, it is ſaid, that apple-trees raiſed on paradiſe-ſtocks, and pears on quince-ſtocks, will frequently bear the ſecond year after grafting, and very generally the third: and as thoſe to be planted in the quarters would be three or four years old before they were removed from the nurſery, they would commence bearing immediately.

Standard apple-trees for orchards ſhould generally be of the tall or high kind, and always grafted upon crab-ſtocks. See ORCHARD and STOCKS.

In ſtandard ſmall fruit-ſhrubs, as the different currant kinds, a great deal depends upon their being properly cut in, as they ſhould be permitted only to produce from ſtuds or ſpurs, and from theſe, after the ſhrubby buſhes are four years old, the young wood being wholly cut away during winter. This method is, however, only neceſſary and applicable to ſtandard currant-ſhrubs, where large fruit is wanted; as when currant-trees are grown againſt walls, and the deſign is to preſerve fruit upon the trees from the period of the currant ſeaſon until the middle of winter, as is the practice in ſome caſes, the mode is to have the fruit rather ſmaller, and the tree larger, and ſo much covered with fruit as to allow of but few ſhoots. Theſe purpoſes are excellently accompliſhed in this way in many places.

Standard foreſt-trees of all ſorts, and deciduous and evergreen ſtandard ſhrubs, ſhould moſtly, when for ornament, be planted out ſingly, or among clumps or groups of low plants, ſo as to produce the beſt and moſt ſuitable effects, according to the nature of the ſituation or place, and the kind of tree or ſhrub which is employed for the purpoſe.

STANDARD *Timber-Trees*, all ſuch deciduous and other trees as are raiſed in woods and other places, trained and left for the purpoſe of forming timber. See TIMBER.

STANDENHEIM, in *Geography*, a town of France, in the department of the Rhine and Moſelle; 9 miles W.S.W. of Creutznach.

STANDIA, called alſo *Dia*, an iſland of the Mediterranean ſea, ſituated three leagues N.E. by E. of Candia. It is about four miles long by two broad; its circumference is irregular; in its ſouth parts are three natural harbours, where ſhips of burden, bound to Candia, caſt anchor and unload a part of their cargo, becauſe the harbour of that town is not deep enough to receive them when they are fully laden. On their departure they alſo go and wait at Dia till boats bring them commodities for completing their lading. The middle harbour, called "Porto della Madona," is the beſt of the three; a veſſel may caſt anchor there in from ſix or eight fathoms water up to a conſiderable depth. On doubling the E. point a fourth harbour occurs, by no means ſafe, rather ſhallow and open to the E. wind, but ſheltered from the S.W. and N.W. Here a merchant veſſel, caught in a gale of wind, might take refuge. This iſland is lofty, rugged, and entirely calcareous. The rock is naked, except towards the ſummit, where the ſoil ſeems to be fit for the culture of the vine and the olive-tree. In various places a whitiſh marble is found; and here are alſo veins, ſeveral feet thick, of ſtreaked alabaſter, which is thought to be of the greateſt beauty. Rabbits are numerous in this iſland; and it has ſome wild goats, in places that are inacceſſible, and alſo ſeveral cats of different colours, that probably belonged to veſſels which have been caſt away. N. lat. 35° 26′. E. long. 25° 9′. Olivier.

STANDIA, a town of European Turkey, in Macedonia, in a ſmall bay of the gulf of Saloniki; 13 miles N. of Lariſſa.—Alſo, a town of Aſiatic Turkey, in Natolia, on the W. coaſt. N. lat. 36° 54′. E. long. 27° 18′.

STANDING, in *Navigation*, denotes the movement by which a ſhip advances towards a certain object, or departs from it: as the enemy ſtands in ſhore, the Engliſh fleet are ſtanding-off, &c.

STANDING, in *Ship-Building*, a term applied to a bevelling that is obtuſe-angled, or without a ſquare.

STANDING *Army*. See ARMY.

STANDING *Coins*. See COINS.

STANDING *of Colours*, is uſed by painters for their durableneſs, in oppoſition to *flying*.

STANDING *Fold*, in *Agriculture*, a term applied to that ſort of fold, made for containing and protecting ſheep, which is of the fixed and immoveable kind, in contradiſtinction to thoſe which are of a moveable nature on land of the arable or graſs kind. See FOLDING *of Sheep*, and SHEEP-*Fold*.

In Suſſex, the ſtanding fold of the late general Murray is ſtated to have been well contrived and formed. It compriſed an incloſed area of fifty-ſeven yards in length, and twenty in breadth, containing one thouſand one hundred and forty ſquare yards: more than ſeven hundred ewes were uſually folded in it during the night, and for that number, it afforded a ſpace of more than a yard and a half for each ſheep. It had all around it a ſhed, nine or ten feet wide, and likewiſe acroſs the middle part, which latter was open on both ſides. There was alſo a rack for hay put up againſt the wall, which was boarded, and ſurrounded the whole of the fold: and another, which was double, to be eaten out of on both ſides, was placed and ſtood all along the central ſhed; under which was a ſmall trough or manger, in which the fine ſorts of food given to the ſheep were put. This was, of courſe, a moſt complete and perfect ſtanding fold for managing and protecting theſe animals, the plan of which may probably in ſome meaſure be imitated by other ſheep-farmers with conſiderable utility and benefit.

STANDING *Marriage*, in the *Law* of Scotland, is uſed to expreſs one actually ſubſiſting, though perhaps reducible for adultery, or liable to be declared void for impotency, or contingency of blood; that is, conſanguinity. Bayne's Crim. Law.

STANDING *Part of the Sheat*, in a *Ship*, that part of it which is made faſt to a ring at the ſhip's quarter. When they ſay, *over-hale the ſheat*, they mean, *hale upon the ſtanding part;* but when they ſay *hale the ſheat* barely, they intend only of the running part.

STANDING *Part of a Tackle*, is the end of the rope where the block is ſeized or faſtened; as the other which is haled is called *fall*.

STANDING *Rigging*, are thoſe ropes which do not run in any block, but are ſet taught, or let ſlack occaſionally, as the ſhrouds, ſtays, back-ſtays, &c.

STANDING *Ropes*. See *Standing* ROPES.

STANDISH, in *Geography*, a poſt-town of America, in the diſtrict of Maine, on the W. line of Cumberland county, between Preſumſcut and Saco rivers; incorporated in 1785, and containing 1378 inhabitants; 18 miles N.W. of Portland.

STANDON, STANTON, or *Stanelow*, is a ſmall market-town and pariſh in the hundred of Braughin, county of Hertford, England, at the diſtance of one mile S.E. from Puckeridge, and 26 N.N.E. from London. It is mentioned by Ingulphus as having been granted to Croyland abbey in the early part of the ninth century; and as the place where abbot Brithmere, about the year 1030, built a ſpacious houſe for the accommodation of himſelf and his retinue, during his journies to London. In this pariſh alſo was a preceptory of knights hoſpitallers, built on lands given with the church to that order by Gilbert de Clare, in the reign of king Stephen: the houſe was deſigned for the reſidence of ſome of the ſiſters of that order, till they were all placed together at Buckland, in Somerſetſhire. The ſcite, and ſome remains of the preceptory, are now connected with a farm-houſe called Friars. The manor, rectory, and advowſon of the vicarage, as parcel of the poſſeſſions of St. John of Jeruſalem, were granted 36 Henry VIII. to ſir Ralph Sadler. A hermitage was founded at Standon by William, an Anchorite, temp. Henry I.; which Richard de Clare, earl of Hertford, gave to the monks of Stoke by Clare, in Suffolk, who are ſaid to have had a cell here, which in after-times appears to have become a free ſecular chapel, and to have been the ſame with the chapel at Salburn in this pariſh. Standon church contains many monuments and ſepulchral memorials. In the eaſtern part of the chancel are the tombs of ſir Ralph Sadler and family: on ſir Ralph's is his effigy in armour lying beneath a canopy, with his children kneeling below. He died in 1587, aged 80. The pariſh of Standon, according to the population return in 1811, contained 1889 inhabitants; the number of houſes being 254. A fair is held annually, and a market weekly, on Fridays.

On Haven-End, an eminence in Standon lordſhip, are two large barrows, ſuppoſed by Salmon to have been raiſed by the Danes. In the neighbouring pariſh of Widford are two other barrows, which give name to the eſtate on which they are raiſed. Beauties of England and Wales, vol. vii. Hertfordſhire, by E. W. Brayley.

STANDS, in *Rural Economy*, a word applied to ſuch young timber-trees as are under ſix inches timber girth, or twenty-four inches in circumference. Theſe are moſtly reſerved in cutting over young timber and other woods.

STANERN, or STANAROW, in *Geography*, a town of Moravia, in the circle of Iglau; 10 miles S. of Iglau.

STANES. See STAINES.

STANESBY, THOMAS, in *Biography*, father and ſon, two ingenious and eminent flute-makers in London during the early part of the laſt century. The flute à bec, or common flute, was ſo much in faſhion during the life-time of the eldeſt Staneſby, who died about the year 1734, that no ſingle ſong was printed without being tranſpoſed into C, or F♮, for the flute, at the bottom of the page. The younger Staneſby, who died in 1754, lived long enough to ſee the common flute totally thrown aſide, in favour of the German flute, a concert inſtrument, an honour which never had been conferred on the common flute, except now and then in the accompaniments of a ſong, ſuch as, "Huſh ye little warbling choir," on the octave flute, and perhaps two or three more may be found in Handel's works.

Staneſby, however, conformed to the taſte of the times, and furniſhed practicians on the flute traverſiere, or German flute, with inſtruments, for which the ſcholars of Weidiman and Ballicourt, the two firſt public players on the German flute in our capital, frequently and loudly called.

Poor Staneſby did not enrich himſelf like Theodorus, a flute-maker at Athens, father of the orator Iſocrates, who acquired wealth ſufficient by his employment, not only to educate his children in a liberal manner, but alſo to bear one of the heavieſt public burdens to which an Athenian citizen was liable, that of furniſhing a choir or chorus for his tribe, or ward, at feſtivals and religious ceremonies.

The ſecond Staneſby was buried in the church-yard of St. Pancras, near London, and on his grave-ſtone there is a very honourable record of the virtues of his private character; a circumſtance which biographers ſhould never neglect to mention, as monumental praiſe is ſeldom laviſhed on perſons of low ſtation: "Why ſhould the poor be flattered?"

STANFALIA, in *Geography*. See STAMPALIA.

STANFORD, or STAMFORD, is an ancient market and borough-town, ſituated at the ſouth-weſtern angle of the county of Lincoln, England, on the banks of the river Welland. One pariſh of the town is in the county of Northampton; but the chief portion of it is built on the ſide of a hill in Lincolnſhire, and when approached from the ſouth, preſents an intereſting and picturеſque appearance. Several old buildings, with towers and ſteeples, are ſeen grouped together. The name of the town is ſuppoſed to be derived from the Saxon *Staen*, and *ford*. According to ſome antiquaries, Stanford was a place of note in the time of Bladud, a Britiſh king, many centuries before the Chriſtian era. The earlieſt authority upon which we can depend, is that of Henry of Huntingdon, a writer of the twelfth century; who relates, that the ancient enemies of England, the Picts and Scots, having ravaged the country as far as Stanford to the ſouth, were there met and defeated by the Saxons under the command of Hengiſt; and that king Vortigern, for ſuch valour, gave to the Saxon leader certain portions of land in the county of Lincoln. Wulphere, king of Mercia, who finiſhed the monaſtery of Medes-hamſted, now Peterborough, in a charter of lands to that abbey in the year 664, aſſigned Stanford as one of its boundaries; and as it roſe progreſſively in importance, ſo in the year 972, in another charter to the ſame houſe by Edgar, it appears to have been more conſiderable than Peterborough. At that period it was a market-town, and is noticed by Leland as afterwards becoming a royal borough: under the Daniſh monarchy it appears ſtill to have maintained the rank which it originally claimed. That it was encircled by walls, and ſecured by gates at an early period, is evident from the Saxon annals terming it Byꞃıᵹh; Florence of Worceſter, Arx; and by Speed's plan, where each is named and delineated. A caſtle was probably erected here by the Danes, as the above-mentioned hiſtorian, Henry of Huntingdon, notices their loſs of it in the year 942 to Edmund Ironſide, and remarks, that it had then been a conſiderable time in their poſſeſſion. Leland, who, on the other hand, adheres to Matthew of Weſtminſter, ſtates that it was rebuilt by Elfreda, ſiſter of Edward the Elder, on the northern bank of the Welland, A.D. 914. Again being poſſeſſed by the Danes, they held it till the deceaſe of their laſt Anglo monarch, A.D. 1041, when the Britons once more became its owners, till William the Norman overcoming the kingdom, in 1066, it devolved to the new monarch and his retainers. The Domeſday ſurvey informs us, that it contained one hundred and forty-one manſions, and twelve lagemen, or civil magiſtrates, who received the forfeitures ariſing from crimes, and held their powers within certain limits. The caſtle, in the time of king Stephen, was beſieged by Henry of Anjou, afterwards the ſecond monarch of that name, who upon taking it beſtowed that and the town, with certain feudal reſervations, on one of his followers, called Richard Humetz, to hold from the crown by homage, tenure, and other ſervices. King John paſſed them to William, earl of Warren, in a ſimilar manner: at his death they were granted by John, who was alſo earl, to Edward I., and paſſed by him again to that nobleman, to revert on his deceaſe once more to the crown. Thus, after many grants and reverſions through forfeiture or failure of male iſſue, it was given by queen Elizabeth to William Cecil, firſt lord Burleigh. Through the marriage of his coheireſs and granddaughter, Anne, with William, earl of Exeter, it paſſed to Henry Grey, firſt lord Stamford, and after continuing in that family ſeveral deſcents, was ſold again to the houſe of Cecil. In Richard III.'s time the caſtle was entirely demoliſhed; and the hill, which was artificially formed by horizontal layers of earth, with the ſlight fragments of a ſtone wall, are all the veſtiges that are now viſible.

In William the Conqueror's reign, Stanford was governed by the lagemen, or aldermen. Edward IV. gave it a privilege it ſtill retains, of ſending two members to parliament, and a charter was granted in the firſt year of that king's reign, when its civic officers were incorporated under the names of the "aldermen and comburgeſſes of the firſt and ſecond bench." Other charters conferred different privileges in ſucceeding reigns, till Charles II. recalling the royal charters throughout the kingdom, gave a new one to Stanford, which was afterwards confirmed by James II. Again incorporated by that deed, it was made to conſiſt of a mayor, thirteen aldermen, and twenty-four capital burgeſſes, by the name of the "mayor, aldermen, and capital burgeſſes, of the town or borough of Stamford."

For parochial and municipal purpoſes, Stanford appears to have been divided, at a remote period, into fourteen wards, or pariſhes; but in 1461, ſome of the churches and houſes were conſumed by fire, by the northern ſoldiers; and the religious edifices were not afterwards re-erected. In 1547, an act of parliament was obtained to divide the northern part of the town into five pariſhes, St. Martin's, or Stanford-Baron, being a diſtinct pariſh. According to the population report of 1811, the borough contained 832 houſes, and 4582 inhabitants; and the pariſh of St. Martin's 163 houſes, and 937 inhabitants.

St. Michael's church, which ſtands near the centre of the town, is ſuppoſed to be the moſt ancient erection, part of it having exiſted antecedent to the year 1230. It has a nave and choir, with north and ſouth aiſles, and chancels which extend beyond the aiſles. The eaſtern end of the choir, which had much decayed, was, about 1705, taken down and rebuilt by the pariſhioners: in the wall were diſcovered various ſculptured ſtones, the remains of ſome more ancient religious building. At the weſtern end of the nave was a wooden tower, which was taken down and replaced by another of ſtone in 1761. The windows of this building were decorated with figures and heraldic ornaments, but it is much to be regretted that they are in a lamentable ſtate of mutilation.

The church of St. Mary appears to have been built towards the latter end of the thirteenth century, and poſſibly upon the ſcite of one much earlier. The upper part of the chancel contains a monument without armorial enſigns, device, or inſcription, but ſimply conſiſting of a ſtatue in armour, lying by the ſide of a female figure. This was erected to the memory of ſir David Phillips, who bravely diſtinguiſhed himſelf in the battle of Boſworth Field.

St. George's church, a large plain building, conſiſting of a chancel, nave, north and ſouth aiſles, with a ſquare embattled tower at the weſt end, was rebuilt, in 1450, by William Bruges, the firſt garter king of arms, who bequeathed many valuable preſents to this building. The remains of David Cecil, high ſheriff of Northamptonſhire in 1542, grandfather of the firſt lord Burleigh, are here entombed.

All-Saints church is a ſtructure well proportioned, and of large dimenſions: it conſiſts of a nave, two aiſles, and chancels; one at the end of the ſouth aiſle, and the other at the eaſt end of the nave. At the weſt end of the north aiſle riſes the ſteeple, a lofty, handſome ſtructure, embattled, with octagonal turrets at the corners, and ſurmounted by a ſpire of a ſimilar form, crocketted at the angles from the baſe to the ſummit. This church was built at the expence of a Mr. John Brown, merchant of the Staple at Calais, who, with his wife, are buried at the upper end of the north aiſle. In the ſame church, where the altar formerly ſtood, are the effigies of William Browne and his wife, who built and endowed the bead-houſe in this town. Againſt the eaſt window, a white marble monument preſerves the memory of Mr. Thomas Trueſdale, who lived in the ſame dwelling with Mr. Brown, and emulated his example, by founding another alms-houſe.

The church of St. John the Baptiſt was rebuilt about 1452, the thirtieth year of the unfortunate Henry VI. It has a nave, and two aiſles, with a chancel at the eaſt end of the firſt, and ſeparated from it by elegant ſcreen-work. The roof has been highly decorated with figures carved both in wood and ſtone; and the windows contained ſome admirable ſpecimens of ſtained glaſs.

Stanford formerly contained ſeveral monaſtic eſtabliſhments; and it is traditionally related that it was, at one time, the ſeat of an univerſity. Hardinge, in his Poetical Chronicles, and in "The Mirror of Magiſtrates," relates the latter circumſtance; but this is not authenticated by better hiſtorians. The only circumſtances which appear to ſupport the idea of an univerſity are, that in the year 1109, Joffrid, abbot of Croyland, deputed three monks from his monaſtery for that purpoſe. Camden remarks, that a violent diſpute aroſe between the northern and ſouthern ſcholars at Oxford, in 1333, when many of the maſters and ſtudents retired to Stanford. Several of theſe, however, ſoon returned to Oxford; and ſome time afterwards, Edward III. iſſued a writ to the ſheriff of Lincolnſhire, commanding him to proclaim at Stanford a prohibition for any perſon to ſtudy or perform ſcholaſtic exerciſes, elſewhere than in the univerſities, on pain of certain forfeitures.

In the reign of Henry III. the Carmelites had a monaſtery here, and gave public lectures on divinity and the liberal arts, with diſputations againſt the Judaic faith. Many of the clergy and higher orders of the people ſent their ſons here for education; and from this poſſibly aroſe a cuſtom, which in ſucceeding centuries was greatly followed. Other religious houſes alſo became ſchools of literature; and by theſe means Stanford became celebrated for liberal inſtruction. The other public inſtitutions of learning, which were ſuppoſed to conſtitute part of the above-mentioned univerſity, were the following: — Brazen-noſe college or ſchool, from which the college at Oxford is ſuppoſed to have derived its name, was built at a remote period, and certainly exiſted early in the reign of Edward III. In 1668 it was taken down, and a charity-ſchool erected on the ſame ſpot:—Sempringham-hall, ſuppoſed to have been founded by Robert Luttrell, in 1262:—Black-hall was of great antiquity, and was taken down ſoon after 1705.

Of Peterborough-hall, Vaudey-hall, the free-ſchool, and other buildings of the ſame nature, but ſlight information can now be gained, excepting that the former was taken down about 1705, and ſtood near All-Saints church; and that the latter was founded in the year 1548, by Mr. William Radcliffe.

The ſchools at preſent ſupported at this place are, the one laſt mentioned, now called Radcliffe's; another inſtituted by Edward Wells, in 1604, denominated Wells's or the petty ſchool; and the blue-coat ſchool.

The ancient and modern inſtitutions for the ſupport of the poor are many in number: the moſt prominent, is one founded by William Browne in the reign of Richard III., already mentioned, which has a chapel at the eaſtern end, conſecrated in 1494; the revenues of which have, of late years, greatly increaſed. Another was erected by the will of Mr. Thomas Trueſdale, in 1700, with endowments bequeathed to it for ever. And, in addition to theſe, are certain charities denominated calliſes; with various other foundations of the like nature.

The principal public building is the town-hall, where the civil buſineſs is tranſacted. It was built by truſtees, under an act paſſed in 1776, near St. Mary's church, when the old hall was taken down. It conſiſts of two handſome fronts, containing twenty apartments, a guard-room, houſe of correction, and a gaol. A ſmall theatre, in St. Mary's ſtreet, was built here in 1768.

The river Welland, which runs to the ſouth of the town, and parts it from Stanford-Baron, is navigable for boats and barges from the ſea to this place. Stanford has a market on Monday and Friday, and ſeven annual fairs.

Stanford-Baron, already named, is ſeparated from the town only by a ſtone bridge, yet it is both a diſtinct pariſh and liberty in the county of Northampton: hence its original name of Stanford beyond the bridge. In 1455 it was held by the abbot of Peterborough, *per baroniam*, and was then firſt denominated Stanford-Baron. In the reign of Athelſtan it had the privilege of a mint, and ſucceeding kings alſo greatly favoured it. Although it cannot now be diſcovered that this pariſh was ever walled, yet it appears to have been defended by five gates and a caſtle, which ſtood on that part of the Roman road now called the nun's farm. This place is deſignated in the Domeſday-book as being the ſixth ward belonging to Stanford, ſituate in Hantuneſcire. In the reign of Henry II. it contained a Benedictine nunnery, dedicated to God and St. Michael, by William, abbot of Peterborough: the annual revenues of this houſe were 72*l*. 18*s*. 10½*d*.

By a deed of the reign of Richard I. notice is taken of an hoſpital for lepers, under the patronage of St. Egidius; and a houſe for knights hoſpitallers: but their founders are now wholly unknown. Where the alms-houſe is now erected, an hoſpital formerly ſtood, dedicated to St. John the Baptiſt. The preſent church is a large, handſome building, dedicated to St. Martin, and founded by biſhop Ruſſell in the reign of Edward IV. It conſiſts of a nave, two chancels, north and ſouth aiſles, and a ſquare pinnacled tower at the weſt end of the former. At the upper end of the north chancel are depoſited the remains of Richard Cecil and his wife, the immediate progenitors of the firſt lord Burleigh; as alſo thoſe of William Cecil, baron of Burleigh, with his effigy in armour on a highly ornamented altar-tomb. In the north chancel is a ſtately and large marble monument, with ſtatues, &c. to the memory of John, earl of Exeter, and his lady, both of whom died in the year 1709.

According to Camden, the cuſtom of borough Engliſh prevails in this manor; by which the younger ſon inherits the lands and tenements poſſeſſed by the parent, when the latter dies inteſtate. Another more ſingular cuſtom, characteriſtic of feudal and ſemi-barbarous times, is ſtill continued at Stanford. On a certain day, annually, about ſix weeks before Chriſtmas, a bull is provided, and deſtined to be hunted by dogs and the loweſt claſs of perſons through the ſtreets of the town. On ſuch occaſions a vaſt concourſe of people is aſſembled, many dogs are brought to the place, and the moſt cruel and wanton acts are reſorted to, in order to irritate the poor animal, and thereby produce what is mis-termed ſport. The bull-running, as it is called, commences early in the morning, after a proclamation is made to guard doors and windows, and warn travellers who are paſſing through the town. The animal is let looſe in the ſtreets, when dogs, men, women, and even children, commence a boiſterous and irritating purſuit. This is ſometimes continued for hours, till the bull is provoked to madneſs. At length he is killed, and the fleſh ſold. It is traditionally related, that this cuſtom originated in the reign of king John, by the order of William, the fifth earl of Warren, who, having obſerved a bull worried through the town by dogs, was ſo much diverted, that he gave a meadow to the butchers of Stanford, on condition that they would provide a bull annually for the ſame purpoſe. A cuſtom ſomewhat reſembling this prevails at Tutbury, in Staffordſhire. See TUTBURY.

About one mile ſouth-eaſt of Stanford is Burleigh or Burghley-houſe, the magnificent ſeat of the Cecil family, and now the property of the marquis of Exeter. The park was incloſed and houſe chiefly built by lord-treaſurer Burleigh, who, in a letter dated 1585, ſays, the "houſe is of my mother's inheritance; and for the building there, I have ſet my walls on the old foundations." On different parts of the edifice are the dates of 1577, 1585, and 1587, pointing out the times when ſuch portions of the houſe were raiſed; but many additions and alterations have been made at ſubſequent periods. The whole preſents a palace-like appearance, and may be ſaid to conſiſt of a maſs of building ſurrounding a ſquare court 110 by 70 feet. In various rooms is preſerved a large collection of pictures by different old maſters, with ſome few paintings by modern artiſts.

The park is of great extent, of varied ſurface, is adorned with much fine timber, a large piece of water near the ſouth front of the houſe; and at the weſtern extremity, adjoining the great North road, is a ſtately lodge of entrance, which was erected in 1801, from the deſigns of Mr. Legg, architect. An intereſting account of this ſeat, with a particular catalogue of the pictures, was publiſhed at Stanford, in 1815, entitled "A Guide to Burghley-Houſe," &c.—Survey of the Town of Stanford, by Butcher, 8vo. 1717. An Eſſay on the ancient and preſent State of Stanford, by Howgrave, 4to. 1720. Antiquarian Annals of Stanford, by Peck, folio, 1727. The Antiquities of Stanford and St. Martin's, by W. Harrod, 2 vols. 12mo. 1785. An Account of the public Schools, Hoſpitals, and other charitable Foundations, in the Borough of Stanford, by Thomas Blore, 8vo. 1813. This is a very intereſting and uſeful work, as calculated to preſerve and give publicity to thoſe benevolent inſtitutions, which were originally intended to afford ſupport to the aged poor, and inſtruction to the lower claſſes of youth.

Stanford, a poſt-townſhip of Ducheſs county, New York, about 18 miles N.E. of Poughkeepſie; incorporated in 1793, and containing 2335 inhabitants. This townſhip is well watered and cultivated; has many able farmers, ſeveral mills, three houſes for worſhip, *viz.* for Quakers, Baptiſts, and Methodiſts. In 1810, its houſehold looms produced 12,680 yards of cloth. Its ſheep were 5564, horſes 811, and cattle 2898.—Alſo, the capital of Lincoln county, Kentucky; ſituated on a fertile plain, about 10 miles S.S.E. of Danville, containing a ſtone court-houſe, a gaol, and about 40 houſes.

STANG, a river of Sweden, which runs into lake Roxan, near Linkioping.—Alſo, a town of Norway; 24 miles N. of Berga.

Stang, in *Rural Economy*, a word provincially ſignifying a long pole, or other piece of wood in the ſame form. Stangs are uſeful for a variety of different purpoſes in the practice of farming.

Stang-*Cart*, in *Agriculture*, that ſort of ſtang which conſtitutes the ſhafts of a cart, or the poles between which the horſe draws. See Cart.

STANGENBERG, in *Geography*, a town of Pruſſia, in Pomerelia; 15 miles S.E. of Marienburg.

STANGENGRUN, a town of Saxony, in the circle of Erzgebirg; 9 miles S.W. of Zwickau.

STANGENROD, a town of Weſtphalia, in the county of Mansfeld; 13 miles N.N.W. of Eiſzleben.

STANGSKAR, a ſmall iſland in the gulf of Finland. N. lat. 59° 45′. E. long. 26° 15′.

STANGWYK, a town of Norway, in the province of Drontheim; 80 miles S.W. of Drontheim.

STANHOPE, George, in *Biography*, an eminent divine of the church of England, was born at Hartſhorn, in Derbyſhire, in 1660. He was educated at Eton, and King's college, Cambridge; and after taking his degrees, and bearing ſome offices in the univerſity, he was preſented by lord Dartmouth, in whoſe family he had been chaplain and tutor, to the rectory of Lewiſham, in Kent. He was appointed one of the chaplains to king William and queen Mary, and retained the ſame office in the following reign. In 1697 he proceeded doctor in divinity, and being at the ſame time diſtinguiſhed for his pulpit eloquence, he was choſen, in 1701, to preach Boyle's lecture; and in 1703 he was promoted to the deanery of Canterbury. He ſometimes preached the lecture at St. Laurence Jewry, in which he attained to great eminence, though he followed many perſons of much celebrity. In 1705 he preached the Latin ſermon before the convocation, of which body he was thrice choſen prolocutor. He died in 1728, at the age of 68. Of the publications of this learned divine, ſome were tranſlations: theſe were "Thomas à Kempis de Imitatione Chriſti;" "Charron de la Sageſſe;" "The Meditations of Marcus Antoninus;" "Epictetus, with the Commentary of Simplicius;" "Rochefoucault's Maxims;" "St. Auguſtine's Meditations." His moſt conſiderable original work was "A Paraphraſe on the Epiſtles and Goſpels," 4 vols. 8vo. ſeveral times reprinted. He alſo publiſhed three ſets of "Sermons on ſeveral Occaſions;" beſides "Sixteen Sermons preached at Boyle's Lectures."

Stanhope, Philip Dormer, earl of Cheſterfield, a nobleman celebrated as a great wit, ſtateſman, and a man of letters, was the eldeſt ſon of Philip, third earl of Cheſterfield, by lady Elizabeth Saville, daughter of George, marquis of Halifax. He was born in London, in September, 1694. He had the misfortune to loſe his mother while he was very young, and being neglected by his father, he was educated under the care of his grandmother, lady Halifax, who proved herſelf quite adequate to the taſk. His elementary inſtructions were received at home from able maſters, who had the advantage of finding in their pupil admirable qualities, and an ardent deſire of excelling in whatever he undertook, and a reſolution to perſevere in the tract in which he entered, without any regard to the obſtacles that might oppoſe themſelves to his progreſs. It is ſaid that lord Galway, diſcerning in him, when very young, a ſtrong inclination for political diſtinction, and at the ſame time a great love of pleaſure, with a propenſity to ſauntering, gave him a friendly leſſon on the abſolute neceſſity of riſing early, in order that he might become a man of buſineſs. The admonition produced ſuch an effect on his mind, that he immediately adopted the practice recommended, and adhered to it during the whole of his life. He was afterwards, by a trifling incident, permanently cured of an impatience of temper, which he was ſenſible would diſqualify him for the character and duties of a ſtateſman. In his 18th year he was entered of Trinity-hall, Cambridge, where he applied himſelf with great aſſiduity to the ſtudies purſued in that ſeat of learning. He was particularly attentive to eloquence, which he was aware was a principal requiſite in a free ſenate; and with the view of becoming a good and a forcible ſpeaker, he marked down all the fineſt ſpeeches of the ancients that came in his way, in the courſe of his reading, and formed his own ſtyle and manner by tranſlating them; a practice which cannot be too warmly recommended to young men likely to come into public life. On quitting the univerſity, this young nobleman made the uſual tour of Europe; and it was at the Hague that he firſt began the cultivation of that enlarged acquaintance with mankind, which has been denominated ſeeing and knowing the world; but with this knowledge he acquired certain pernicious propenſities, which adhered to him through life: among others was that of gaming. A viſit of ſome length to Paris further contributed to faſhion his manners, and to render him at length that model of true politeneſs, which he exhibited in after-life to his admiring countrymen. This was about the time of the demiſe of queen Anne, and he did himſelf high honour by the aſſertion of thoſe principles of freedom which effected the ſucceſſion of the houſe of Hanover, and which, during the whole of his political life, he ſteadily maintained. On his return to England in 1715, he was preſented to the new ſovereign, and appointed one of the gentlemen of the bed-chamber to the prince of Wales. He was elected member of parliament for one of the Corniſh boroughs, in the firſt parliament of George I., and commenced a ſpeaker in the debate reſpecting the impeachment of the perſons concerned in the peace of Utrecht. Upon this occaſion he manifeſted a juvenile violence, which produced an intimation from the oppoſite ſide, that advantage would be taken of his being under the lawful age for ſitting in parliament. Upon this hint he immediately quitted the houſe, and ſet off for Paris. On his return, he was ſometimes the defender and ſometimes the opponent of miniſterial meaſures; but his talents, at this time, do not appear to have made much impreſſion on the houſe or the country. In reward, however, for his ſupport of a motion for the augmentation of the army, he was, in 1723, made captain of the yeomen of the guards; and it was a proof of his diſintereſtedneſs, that when adviſed by his predeceſſor, lord Townſend, to make the poſt more profitable than he had done, by the ſale of ſubordinate places, he replied, "I rather wiſh, in this inſtance, to follow your lordſhip's example than your advice." He was diſmiſſed from this office in 1725; and in the following year, on the death of his father, with whom he had never been on terms of cordiality, he entered the houſe of lords, and joined the oppoſition. To this aſſembly his talents were better adapted than to the houſe of commons. His eloquence, the fruits of much ſtudy, was leſs characterized by force and compaſs than by elegance and perſpicuity, and eſpecially by good taſte, and a vein of delicate irony, which, while it ſometimes inflicted ſevere ſtrokes, never paſſed the limits of decency and propriety. "It was that of a man, who, in the union of wit and good ſenſe with politeneſs, had not a competitor." Theſe qualities were matured by the advantage of a familiar acquaintance with almoſt all the eminent wits and writers of his time; many of whom had been the ornaments of the preceding age of literature, while others were deſtined to become thoſe of a later period. He knew how to appreciate genius and talents, and was the friend of Pope, and received him in almoſt all his ſelect parties at Twickenham, where he met the firſt nobility in aſſociation with the moſt diſtinguiſhed votaries of the muſes.

Soon after the acceſſion of George II. lord Cheſterfield was nominated ambaſſador at the Hague. Scarcely was any man ever better adapted than his lordſhip to fill a diplomatic ſituation, as well on account of his natural acuteneſs, and of his conciliating manners, as his familiarity with the modes and uſages of general ſociety. He was, however, at this time but little acquainted with public buſineſs; but poſſeſſing the laudable ambition of rendering himſelf fully maſter of whatever he undertook, he ſpared no pains to acquire the knowledge for the poſt in which he was placed, and which at that time was a very important one; the Hague being, in fact, the centre of the principal political negociations carrying on throughout Europe. In the year 1730 he was appointed high ſteward of the houſehold, and he was, at the ſame time, decorated with the order of the garter. He now returned to Holland, and was inſtrumental in forming an important treaty between the courts of London and Vienna, and the States-general. In 1732 he obtained his recall; and on his return, he ſupported the plans of the prime miniſter, though there does not appear to have been any cordiality between them; and when ſir Robert Walpole introduced his famous exciſe meaſure, the earl ſpoke againſt him with all his force, and thereby gave ſo much offence that he was deprived of his offices, and he again joined the party in oppoſition. He married, in 1733, the counteſs of Walſingham, niece or probably daughter to the ducheſs of Kendal, who had been miſtreſs to George I. She was a lady of great merit and accompliſhments, and by her prudence contributed very much to retrieve the deranged affairs of her lord. The noble earl did not neglect to pay his court to the prince of Wales, who attached himſelf to the oppoſers of his father's government. Of his oratorical exertions, none was more generally admired than his ſpeech againſt the bill for granting to the lord chamberlain the power of licenſing dramatic performances. In 1741, his health being much impaired, he was adviſed to make the tour of the continent. In his way to the Spa, he ſaw, at Bruſſels, Voltaire, with whom he had contracted a friendſhip in England. At Spa his reputation, and the urbanity of his manners, drew upon him much flattering notice from perſons of diſtinction; and the manner in which he ſpoke of the riſing Frederick of Pruſſia to the envoy of that monarch, procured for him a preſſing invitation to the court of Berlin, which he would gladly have accepted, had he not been prevented by other engagements. A ſhort ſtay at Paris introduced him to the moſt diſtinguiſhed of both ſexes for rank and talents in that capital, where he was equally gratified and admired.

His ſtay in the ſouth of France was ſhortened by the ſtate of political affairs at home. The attempts of France to ruin the houſe of Auſtria were threatening deſtruction to what was denominated the balance of power in Europe; and the miſcarriages of the Engliſh miniſters in their political meaſures ſpread diſcontent through the nation. This at length produced the fall of that ſtateſman, who had ſo long ruled the public councils; and a new adminiſtration was formed, in which lord Cheſterfield had no place. This omiſſion was probably owing, in great part, to the perſonal diſlike of the king, who could not forget the ſevere things he had ſaid with reſpect to the royal partiality to the intereſts of Hanover, and the ſacrifices made of the intereſts of Great Britain to thoſe of the electorate. He took an active and moſt decided part in oppoſition to the meaſures of the miniſtry, and was ſaid to be particularly happy in his ſpeech againſt the gin-licence bill, and againſt that for continuing attainders upon the poſterity of perſons convicted of high treaſon. This laſt bill was introduced in conſequence of the proſpect of a new rebellion, promoted by France, and which ſoon after took place. This event produced a change in the miniſtry, and lord Cheſterfield was ſent out as ambaſſador to the United Provinces; a ſtation which he had before occupied with much reputation. He effected the purpoſe for which he was ſent, *viz.* that of engaging the Dutch to concur in earneſt in the war againſt France; and returned in 1745, at the time of the breaking out of the rebellion in Scotland. He was immediately nominated to the high ſtation of lord lieutenant of Ireland; an office of great importance at this period, when there was cauſe of apprehenſion from the prevalence of the Roman Catholic religion in that iſland. He ſet off for his government in the end of Auguſt, taking with him a ſecretary, who had not enjoyed any advantage from experience, and to whom he ſaid in a tone of deciſion, "Sir, you will receive the emoluments of your place, but I will do the buſineſs myſelf, being determined to have no firſt miniſter." In a ſimilar ſpirit he openly declared, that if any one, during his ſtay in Ireland, ſhould make a ſucceſsful application for a place in the king's gift through any channel but his own, he would immediately throw up the lieutenancy. With theſe reſolutions he began his adminiſtration; and by vigour on the one hand, and conciliation on the other, by ſtrict integrity, and a frank undiſguiſed ſyſtem of policy, he kept every thing quiet in that kingdom, while the ſiſter iſland was over-run with terror and commotion. Inſtead of abridging the Catholics of their religious liberty, he favoured and augmented it; wiſely judging, that the more openly they ſhewed themſelves in attendance at their own places of worſhip, the leſs their ſecret machinations were to be regarded. He, however, kept a vigilant eye upon all their proceedings, but diſcouraged idle ſuſpicions and malicious informations. A zealous Proteſtant once came, very officiouſly, as the noble lord thought, to inform him that one of his coachmen went privately to maſs. “Does he?” ſaid the lord lieutenant: “I will take care that he never drives me thither.” Such, ſays his biographer, was lord Cheſterfield's conduct in his vice-royalty, that he quitted it with the regret of all parties; and that, to this day, the ſpirit of his adminiſtration is regarded as a model for all who are entruſted with that important ſtation. He returned to England in April, 1746, when the rebellion was terminated by the victory gained at the battle of Culloden.

He now accepted the office of ſecretary of ſtate, with the duke of Newcaſtle as his colleague. Never approving, in his own mind, of the war in which the nation was engaged, and conſtantly wiſhing for peace upon reaſonable terms, he was nevertheleſs carried away, by a ſuperior influence in the cabinet, to concur in the meaſures of the court, till their ill ſucceſs induced him to draw up a ſtrong memorial, which being diſregarded, he reſigned his place in February, 1748, and never afterwards joined in any adminiſtration. From this period till his death he lived as a private nobleman, attached to the arts and to letters, and was looked up to throughout Europe as inferior to none of his high rank for brilliancy of wit, and the poliſh of cultivated ſociety. Being ſeized with a deafneſs in 1752, that incapacitated him, in a meaſure, for the pleaſures of ſociety, he led a retired life, amuſing himſelf with his books and his pen. He engaged rather largely as a volunteer in a periodical work, entitled “The World,” in which his contributions have a diſtinguiſhed degree of excellence. His lordſhip maintained a character for wit and talents that has few equals. He rendered himſelf illuſtrious, as we have ſeen, by his eloquence in parliament, on many important occaſions, of which there is a characteriſtic inſtance of his own relating. He was an active promoter of the bill for altering the ſtyle; on which occaſion, as he himſelf relates in one of his letters to his ſon, he made ſo eloquent a ſpeech in the houſe, that every one was pleaſed, and ſaid he had made the whole very clear to them; “which,” ſays he, “God knows, I never attempted. I could juſt as ſoon have talked Celtic or Sclavonian to them as aſtronomy, and they would have underſtood me juſt as well.” The high character which lord Cheſterfield had ſupported through life received no ſmall injury, ſoon after his death, from a full diſplay of it by his own hand. He left no iſſue by his lady, but had a natural ſon, named Philip Stanhope, whoſe education was, for many years, a cloſe object of his attention; and who was afterwards envoy extraordinary at the court of Dreſden, but who died before his father. After the death of the earl of Cheſterfield, Mr. Stanhope's widow publiſhed a courſe of letters, written by the father to the ſon, filled with inſtructions ſuitable to the different gradations of the young man's life to whom they were particularly addreſſed. Theſe letters have been highly applauded, and as loudly condemned. They contain many admirable obſervations on mankind, and rules of conduct; but the author lays a greater ſtreſs on exterior accompliſhments and addreſs than on intellectual qualifications and ſincerity, and allows a much greater latitude to faſhionable pleaſures than ſound morality will admit. It has been urged in excuſe for the author, that he never intended theſe letters for publication: they contained inſtructions for a particular individual, and they do not pretend to touch upon the more weighty points of morals, theſe being left to the inculcation of a ſelected tutor: nevertheleſs, there is ſome occaſional advice coming under this head, contained in the later letters, when the ſon was already launched upon the world, which have juſtly ſubjected the writer to ſevere animadverſion. Of theſe, ſuch as relate to truth in the commerce of ſociety, under the diſtinctions ſimulation and diſſimulation, have been defended and juſtified by politicians, as abſolutely neceſſary for one who was to be trained to diplomatic habits. But the ſame apology cannot be made for a father's attempts to faſhion his ſon to politeneſs, by recommending connections with married women, which, however lightly regarded in the licentious courts and capitals at which he himſelf had been a viſitor and reſident, muſt ever be conſidered as a moſt ſerious violation, not only of the laws of God, but of private friendſhip, and of the moſt ſacred bond of ſocial life. Theſe obnoxious parts would, in all probability, have been ſuppreſſed, had the author reviſed and publiſhed his own letters. On the other hand, there are, in the courſe of the volumes and the other works of lord Cheſterfield, many examples of his uſeful and efficacious endeavours to ſerve the cauſe of morality. His lordſhip died in March, 1773, in the 79th year of his age. He had for ſome time been extremely infirm, and having outlived moſt of his friends and contemporaries, he was in fact reduced to a ſtate in which he rather patiently endured life than enjoyed it. “It is unneceſſary,” ſays his biographer, “to add any thing to the view already given of his moral character: if it was very far from faultleſs, it certainly exhibited many excellencies, which enabled him to perform important ſervices to his friends and country. In his literary capacity, he poſſeſſed wit, good ſenſe, and a fine taſte, in an uncommon degree. His ſtyle is of the pureſt Engliſh.” Of his works, which, beſides thoſe already referred to, contain papers in ſome of the political journals of the day, ſpeeches, ſtate papers, and letters, French and Engliſh, a Collection, in 2 vols. 4to. with memoirs of his life, by Dr. Maty, was publiſhed in the year 1777, to which the reader is referred for more minute information relating to the character, exertions, and works of the earl of Cheſterfield.

STANHOPE, JAMES, earl, a celebrated Engliſh nobleman, ſtateſman, and general, deſcended from a very ancient family in the county of Nottingham, eldeſt ſon of Alexander Stanhope, only ſon of Philip, the firſt earl of Cheſterfield, was born in the year 1673. He entered at a very early period into the army, and ſerved under king William in the war againſt France, during which, and particularly at the ſiege of Namur, he diſtinguiſhed himſelf ſo much to the king's ſatisfaction, as to receive from his majeſty a company of foot, and ſoon after a commiſſion as colonel of the 33d regiment. In the war which was undertaken for the purpoſe of placing Charles II., ſon of the emperor Leopold, on the throne of Spain, colonel Stanhope, while commanding a regiment of foot, in 1704, at Porta Legra, in Portugal, was ſurrounded by king Philip's army, and he and his whole regiment were made priſoners of war. Being exchanged, he was in the following year promoted to the rank of brigadier-general, and in the next campaign he gained very conſiderable reputation at the ſiege of Barcelona, under the command of lord Peterborough. General Stanhope planned and completed the conqueſt of the iſland of Minorca. Having landed about ten miles from St. Philip's fort, on the 26th of Auguſt, with 3000 men, the general cauſed batteries to be erected, and ordered a number of arrows to be ſhot into the place, in which papers were ſtuck, written in the Spaniſh and French languages, containing threats that the whole garriſon ſhould be ſent to the mines, if they did not immediately ſurrender. The garriſon conſiſted of 1600 men, commanded by colonel La Jonquiere. So artfully had general Stanhope drawn up his men, as to impreſs the minds of the enemy with the idea, that they were beſieged by an army of at leaſt 10,000 ſoldiers. The ſtratagem had the deſired effect. On the third day the garriſon capitulated; and ſo completely mortified was the Spaniſh governor when he learned the real number of the beſiegers, that he threw himſelf out of a window in deſpair, and was killed on the ſpot. La Jonquiere was impriſoned for life, and the other French officers incurred their monarch's diſpleaſure. In 1710, general Stanhope headed the allied troops, killed the Spaniſh commander with his own hand, and placed the victorious banners of England upon the walls of Madrid; but before the end of the year the general experienced a reverſe of fortune, and he, with 2000 choice Britiſh troops, were made priſoners of war at the town of Brihuega. On this account he incurred the cenſure of the houſe of lords. Soon after the arrival of king George I. general Stanhope was appointed one of the principal ſecretaries of ſtate, and a member of the privy council. He was alſo employed in ſeveral highly important negociations. In the year 1717 he was appointed firſt lord of the treaſury, and chancellor of the exchequer; and in a very ſhort time afterwards, he was raiſed to the peerage of Great Britain. On the 13th of December, 1718, earl Stanhope brought into the houſe of peers a bill for the repeal of ſome clauſes in the Corporation and Teſt acts, which, after a violent oppoſition, was carried through both houſes, and received the royal ſanction. This nobleman, diſtinguiſhed in the ſeveral capacities of general, ſtateſman, and ſenator, died in the year 1721, deeply regretted by the king, whoſe favourite miniſter he had been, and greatly reſpected by the nation at large, for whoſe intereſts he had ever manifeſted an unwearied and truly diſintereſted zeal.

Stanhope, Philip, brother of the foregoing, was brought up to the ſea-ſervice, and in 1704 was promoted to the command of the Haſtings frigate, as ſucceſſor to captain Charles Parſons. After this he was appointed captain of the Milford, in which ſhip he was ſerving under ſir Staford Fairborne at the ſiege of Oſtend, and choſen by that commander to bear to England the news of its ſurrender. Not long after he was ſent to the Mediterranean, where he was employed under the command of captain Coney. He continued in the ſame command during the remainder of his life; which, ſays his biographer, exceſſive gallantry, added to a degree of fraternal love almoſt unequalled, rendered, alas! too ſhort. Frequent mention is made of him in hiſtory, and the private journals of officers more particularly connected with him in ſervice and command, as an active, diligent, and intelligent officer. In Auguſt, 1708, being left under the command of captain Hubbard, it was determined at a council of war, held on board the Elizabeth at the requeſt of the king of Spain, that the York and Milford ſhould aſſiſt in conveying the tranſports, which had on board lieutenant-general Stanhope and a ſtrong body of troops, from Catalonia to Minorca. The reduction of this iſland was not only become a very favourite object with the king of Spain, but was regarded as likely to be extremely conducive to the ſucceſs of the allied cauſe. General Stanhope, who commanded the land forces deſtined for this expedition, was, as has been intimated, the elder brother of this gentleman, and the ties of conſanguinity appeared to increaſe the thirſt of glory, and ſtimulated the latter to ſhare with the former in danger, as, though a younger, he appeared a ſcarcely leſs ambitious candidate for fame and military glory. Attending the land-forces as a volunteer at the aſſault of the Spaniſh lines at Fort Mahon, he there fell in the moment of victory, on the 17th of September, 1708. Campbell's Admirals.

Stanhope, Philip, earl, ſon of the foregoing, born the 15th of Auguſt, 1714, ſucceeded to his father's titles when he was only ſeven years old. He was, by the will of his father, confided to the guardianſhip of Philip Dormer, the celebrated earl of Cheſterfield, of whom we have already ſpoken. This nobleman, as we have ſeen, was ſo ſtrongly attached to the ſtudy of the belles-lettres and claſſical purſuits, as to hold very cheap every other ſpecies of learning; and in conformity with this diſpoſition, he abſolutely prohibited his young relation and ward from mathematical ſtudies, for which he manifeſted, while very young, a natural and ſtrong attachment. Notwithſtanding this injunction, the young lord, when advanced to more mature years, applied himſelf to his favourite ſtudy with ſo much avidity, as to become one of the firſt mathematicians of the age. His predilection, however, for the ſciences, properly ſo called, did not prevent him from attaining the moſt profound and extenſive knowledge of the ancient claſſics. At no very advanced period of his life, he was a complete maſter of the Latin and Greek languages, and could, without the ſmalleſt heſitation, repeat the whole of the Iliad, and the Odyſſey of Homer, in the original language. He diligently cultivated an acquaintance with the poets and hiſtorians of antiquity through the whole of his life, ſpending ſeveral hours of each day either in claſſical reading, or in the inveſtigation of theorems in the higher and more ſublime branches of geometry. Earl Stanhope acquired, likewiſe, a complete knowledge of many modern languages, in which he could maintain a converſation with as much fluency, as if they had been his vernacular tongue.

A perſon ſo formed for the purſuits of literature and ſcience in all its various branches, would, it may be eaſily conceived, have no great ambition to be diſtinguiſhed as a politician and ſtateſman. He was, in truth, a man of the moſt undeviating integrity, and his principles could in no inſtance be brought to bend to circumſtances, nor be ſwayed by any motives from the ſtrict line of rectitude. In the year 1742 we find him in his place in the ſenate, when the ſeveral eſtimates of the expence occaſioned by foreign troops in the pay of Great Britain were taken into conſideration. His lordſhip then, at the cloſe of an excellent and pathetic ſpeech, moved for an addreſs to adviſe and beſeech his majeſty, "that, in compaſſion to his people, already loaded with ſuch numerous and heavy taxes, ſuch large and growing debts, and greater annual expences than the nation at any time before had ever ſuſtained, he would exonerate his ſubjects of the charge and burthen of thoſe mercenaries, who were taken into the ſervice laſt year without the advice or conſent of parliament."

Earl Stanhope's name is likewiſe enrolled among thoſe of many other patriotic noblemen in ſeveral proteſts againſt meaſures, which appeared to his mind hoſtile to the conſtitution of his country, and the real intereſts of public liberty. It was either in the earlier attempts made by the miniſters of his preſent majeſty to ſubjugate America, or on the queſtion of the Middleſex election, that this nobleman travelled from Geneva, where he reſided ſeveral years, to give his vote againſt the meaſure, and finding his exertion of no avail, he ſoon after returned to the continent, to enjoy domeſtic privacy among his family and his books. At this period his lordſhip, whoſe dreſs always correſponded to the ſimplicity of his manners, was once rather rudely prevented from going into the houſe of peers by a door-keeper, who was unacquainted with his perſon. Lord

Stanhope perſiſted in endeavouring to get into the houſe, without ſtopping to explain who he was: and the door-keeper, determined alſo on his part, made uſe of theſe words: "*Honeſt man*, you have no buſineſs here:—— *Honeſt man*, you *can* have no buſineſs in this place."

In 1774, earl Stanhope took his leave of Geneva, where he had ſpent about ten years, greatly reſpected and beloved by all the reſpectable people of that city. His lordſhip's extenſive hoſpitality and beneficence are ſtill remembered with affection and gratitude by many of the inhabitants of that ſmall republic. From this period his lordſhip took but a very ſmall ſhare in the public tranſactions of the country. He divided his time between his town reſidence and his ſeat at Chevening, in Kent, devoting himſelf cloſely for ſeveral hours in the day to claſſical and mathematical ſtudies, which had long become his habitual amuſement.

It is to be deeply regretted, that learning ſo profound and talents ſo rare ſhould have been applied almoſt entirely to his own gratification, and that he had not conſecrated part of his time to the publication of the reſult of thoſe reſearches, which engaged his attention for more than half a century. To his lordſhip's munificence, however, the public are indebted for the poſthumous works of Dr. Robert Simſon (ſee his article); which were printed at his own expence, and a copy or copies of which were ſent to every learned ſociety in Europe, and alſo to many of the moſt diſtinguiſhed mathematicians both of his own and foreign countries. It appears, likewiſe, that Dr. Simſon was indebted to this nobleman for the ninety-eighth propoſition of Euclid's data. To him alſo the public are under conſiderable obligations for the moſt complete and magnificent edition of the works of the illuſtrious Archimedes, which was prepared for the preſs by the learned Joſeph Torelli of Verona, and which was printed in 1792, at the Clarendon preſs, Oxford.

From the circumſtance of many valuable works of ſcience being dedicated to earl Stanhope, the ſubject of this article, among which were Dodſon's Logarithms, and the third volume of Dr. Prieſtley's Experiments on Air, and other branches of Natural Philoſophy, we may infer that he was the patron of ſeveral learned men. His lordſhip died the 7th of March, 1786, leaving behind him a ſon, the preſent earl, well known in the political as well as the ſcientific world, and a widow, with whom he had lived forty-one years. This lady, who ſurvived the earl twenty-three years, was Grizel, the daughter of viſcount Binning, ſiſter of the late, and aunt to the preſent earl of Haddington. She was endowed with a fine underſtanding, which ſhe had cultivated and improved by the conſtant peruſal of the beſt authors in the Engliſh and French languages. She died, in the full poſſeſſion of her faculties, at the advanced age of ninety-ſix. It is a remarkable fact, that a year or two previous to her deceaſe, ſhe cut a ſet of new teeth, and had her hair renewed. She devoted much of her long life to acts of benevolence. The writer of this article was honoured with her acquaintance, and he hopes he may add with her friendſhip, during ten years of his life, and he will never ceaſe, while in poſſeſſion of his mental faculties, to reverence her memory, and to hold in high eſtimation her talents and virtues.

STANHOPE, in *Geography*, a market-town and extenſive pariſh in the N.W. diviſion of Darlington ward, in the county palatine of Durham, England, is ſituated on the northern banks of the river Wear, 21 miles W. from Durham, and 264 N.N.W. from London. The privilege of a market was granted by cardinal Langley in the year 1421, and having fallen into diſuſe, was revived by letters patent in 1669, through the influence of Dr. Baſire, the then rector, and is now held on Fridays. Here were two annual fairs, but they are diſcontinued. The church is an ancient, plain ſtructure, ſtanding on a riſing ground to the north of the town. The rectory is worth about 2000*l. per annum.* On the weſt ſide of the town is an eminence, called Caſtle-Hill, which riſes from the Wear to the height of 108 feet. The ſummit is of an oblong figure, thirty paces in width, divided by a ditch: another ditch defends the acclivity to the north and eaſt, where the aſcent is eaſieſt. It is traditionally ſaid to have been a fortreſs of remote origin, demoliſhed during the incurſions of the Scots. The pariſh of Stanhope, beſides the town, includes the diſtricts of Stanhope-Foreſt Quarter, and Stanhope-Park Quarter, as alſo the townſhip of Newlandſide. The whole, according to the population returns of the year 1811, contained 1011 houſes, occupied by 6376 perſons, moſt of whom are employed in the neighbouring lead-mines. Near the town, on the north, is a cavern, extending under ground nearly a mile, and ſaid to abound with ſtalactites.

At a ſhort diſtance weſt of the town is a ſpacious old fabric, called Stanhope Hall, formerly the manor-houſe of the ancient family of Featherſtonehaugh, the laſt of whom was ſlain at the battle of Hockſtet.

Stanhope park, a large tract of elevated land, about twelve miles in circumference, is an appendage to the ſee of Durham, where the biſhop anciently held his great foreſt-hunts, and had his maſter of the foreſt, his bow-bearer, and other ſubordinate officers. Leland mentions this park as being "rudely incloſed with ſtone."

St. John's Weardale is only a chapelry to Stanhope, but has the privilege of a market, eſtabliſhed for the benefit of the workmen employed in the lead-mines. It is ſeated in a narrow part of the vale, on the ſouth of the Wear. Beauties of England and Wales, vol. v. by John Britton, F.S.A. and E. W. Brayley.

STANHOPE *Preſs*. See PRINTING.

STANIHURST, RICHARD, in *Biography*, a divine and hiſtorian, was born at Dublin about the year 1545, of which city his father was recorder. He was educated at the Univerſity college, Oxford, after which he came to London, and ſtudied the law in Furnival's Inn, and then at Lincoln's Inn. Returning to Ireland, he practiſed ſome time at the bar; but having abandoned the Proteſtant for the Roman Catholic religion, he thought it neceſſary to remove to the continent, for the purpoſe of obtaining a freer exerciſe of the duties which he owed to his Maker. After this he entered into orders, and became chaplain at Bruſſels to Albert, archduke of Auſtria. He died in 1618, having obtained a very high reputation for learning. His writings are enumerated as follow: "Harmonia, ſeu Catena dialectica in Porphyrium;" "Deſcriptio Hibernicæ," inſerted in Holingſhed's Chronicle; "De Rebus in Hibernia geſtis. Lib. IV." In this work we are told he took Giraldus Cambrenſis for his guide, and he is ſaid to have adopted freely the erroneous ſtatements of that writer, though in ſome places he has corrected him from other writers. He publiſhed likewiſe "A Life of St. Patrick," and ſeveral Catholic works: of theſe, one was entitled "Brevis Præmonitio pro futura Concertatione cum Jacobo Uſſerio." This was occaſioned by a work of Dr. Uſher, afterwards the celebrated primate of Ireland, who was a nephew of Stanihurſt: our author did not, however, live to finiſh the reply thus announced. Mr. Stanihurſt tried his powers as a poet, by a verſion of the four firſt books of Virgil's Æneid in Engliſh hexameters. It is remarkable for the uncouthneſs of its diction and verſion. It is mentioned by Warton, who acknowledges that Mr. Stanihurſt, with all his fooliſh pedantry, was certainly a ſcholar. He had a ſon, who became a Jeſuit, and wrote various moral and religious works.

STANISLAUS I., Leizinski, king of Poland, born at Leopold in 1677, was ſon of a diſtinguiſhed Poliſh noble, who, after occupying ſeveral important poſts, was raiſed to that of grand treaſurer of the crown. His ſon, the ſubject of this article, diſplayed at a very early period talents and diſpoſitions which announced a character equally amiable and eſtimable. "His countenance," ſays his biographer, "expreſſed courage joined with ſweetneſs, together with that air of openneſs and ſincerity which is more perſuaſive than eloquence itſelf. He was brave, and enured to hardſhip and fatigue. He ſlept on a ſtraw matraſs, required ſcarcely any perſonal ſervices from his domeſtics, was temperate, economical, adored by his vaſſals, and beloved by his friends." When Charles XII. of Sweden entered Poland, for the purpoſe of dethroning Auguſtus, Staniſlaus, then palatine of Pomerania, was deputed to that prince from the confederation of Warſaw. In the conference with the monarch, he appeared to him in ſo favourable a light, that the Swede immediately took the reſolution of raiſing him to the crown of Poland, which was effected at an election held July 12, 1704, when Staniſlaus was in his twenty-ſeventh year. The unexpected entrance of Auguſtus into Warſaw, when the king of Sweden was at a diſtance with his army, obliged Staniſlaus to make a precipitate retreat: but by another change he was brought back, and crowned at Warſaw with his wife, in October 1705, and by a treaty in the following year, Auguſtus was compelled ſolemnly to abdicate the crown of Poland in favour of his rival. Staniſlaus remained poſſeſſor of the kingdom till the fatal defeat of his patron Charles, at Pultowa, in July 1709. Being now unable to maintain himſelf in Poland, he withdrew with the Swedes into Pomerania, and thence croſſed into Sweden, where he paſſed ſome time in retirement, while negociations were carrying on to reſtore the peace of the north. As his abdication of the Poliſh crown ſeemed a neceſſary preliminary, he readily ſignified his own concurrence, and wrote to Charles at Bender to obtain his conſent. Not being able, by letter, to perſuade him, he reſolved to try the effect of a perſonal conference; and accordingly aſſumed a feigned name, and, accompanied by two officers, proceeded for the frontiers of Turkey. On his arrival in Moldavia he was arreſted, and brought before Hoſpodar, who diſcovered his true perſon, and ſent him to Bender, where he was detained as a priſoner, but was extremely well treated. He was ſuffered to depart in 1714, when he went to Deux Ponts, where he was joined by his family. A Saxon officer made an attempt to aſſaſſinate him, but the deſign was diſcovered before it could be put into execution, and he pardoned and diſmiſſed the conſpirators. In 1719 he received intelligence of the death of Charles XII., and feeling himſelf now deprived of his protector, he applied to the court of France, which gave him a retreat in Alſace. Here he lived in a ſtate of great obſcurity, until his daughter, the princeſs Mary, was unexpectedly choſen as queen to Lewis XV. This was in the year 1725, when Staniſlaus removed to the caſtle of Chambord. On the death of Auguſtus in 1733, an attempt was made by the French monarch to replace Staniſlaus on the Poliſh throne, and he repaired to Dantzic, in order to ſupport the party which actually proclaimed him; but his competitor, the ſon of Auguſtus, and elector of Saxony, favoured by Auſtria and Ruſſia, was more ſucceſſful, and Staniſlaus was obliged to quit Dantzic in diſguiſe, and through many dangers eſcaped to Konigſberg. He ſupported this reverſe of fortune with philoſophical reſignation, and at the peace of 1736 he formally abdicated all claim and pretenſions to the kingdom, on condition of retaining the title, and being put into poſſeſſion for life of the duchies of Lorraine and Bar. Thenceforth he lived as the ſovereign of a ſmall country, which he rendered happy by the exerciſe of virtues, that cauſed him to be named by the general voice of his ſubjects, "Staniſlaus the Beneficent." Inſtead of impoſing new and oppreſſive taxes, he relieved his people from the preſſure of many which they had heretofore borne; yet he was able, by a prudent economy, to found many uſeful and charitable eſtabliſhments, and to patronize the arts and ſciences. He was himſelf attached to literature, and wrote various treatiſes on moral, philoſophical, and political topics, which were publiſhed under the title of "Œuvres du Philoſophe Bienfaiſant," 4 vols. 8vo. Theſe volumes were publiſhed in 1765, and the royal author of them died in the following year, univerſally lamented.

Stanislaus-Augustus, Poniatowski, king of Poland, was the ſon of count Poniatowſki, a Lithuanian, who, after being in the ſervice of Charles XII. of Sweden, and of Auguſtus, king of Poland, married the princeſs Czartorinſka, a deſcendant of the great family of the Jagellons. Staniſlaus poſſeſſed a fine perſon, and a graceful demeanour, and was well received in the various parts of Europe which he viſited while he was young. From England he accompanied the ambaſſador to Ruſſia, where he acquired the particular favour of Catharine, then grand ducheſs. When ſhe came to the crown, ſhe exhibited her attachment by reſolving to raiſe him to the throne of Poland on the death of Auguſtus III., and by means of a body of Ruſſian troops, his election was carried in the plain of Vola, on the 7th day of September, 1764, when Staniſlaus was in his thirty-ſecond year. His talents and excellent diſpoſition gave promiſe of a reign happy to himſelf and proſperous to his country; but the overbearing influence by which he had been elected, and the radical vices of the Poliſh conſtitution, acted as perpetual cauſes of tumult and diſſention, and thwarted all the expectations and hopes that had been formed of the government of Staniſlaus. The firſt diſorders in this reign aroſe from religious differences. The non-catholics, compriſed under the general name of Diſſidents, had been conſtantly oppoſed in their claims of equal civil rights by the Romaniſts, and had been obliged to apply for protection to the Proteſtant powers and the court of Ruſſia, who were guarantees of the treaty of Olivia, by which their privileges had been ratified. In 1766, at a diet, the miniſters of theſe powers had preſented memoirs in favour of the Diſſidents, and the king ſeemed inclined to ſupport their cauſe, while the Catholic prelates and nobles violently oppoſed them. The empreſs of Ruſſia interfered effectually by ſending troops into Poland, which advanced to the gates of Warſaw. Confederacies ſtarted up to reſiſt them, and the country was plunged into civil war. The king was quite unable to quell theſe diſorders, being regarded as having been impoſed on the nation by a Ruſſian force, and in 1771 an extraordinary attempt was made on his perſon, of which a very intereſting account is given in the firſt volume of Coxe's Travels into Poland, which is thus concluded: "So extraordinary an eſcape is ſcarcely to be paralleled in hiſtory, and affords ample matter of wonder and ſurpriſe. Scarcely could the nobility or people at Warſaw credit the evidence of their ſenſes, when they ſaw him return. Certainly neither the eſcape of the king of France from Damien, nor of the king of Portugal from the conſpiracy of the duke d'Aveiro, were equally amazing or improbable as that of the king of Poland."

This attempt on the life of his majeſty was planned by a

Poliſh nobleman named Pulaſki, who engaged three other chiefs by a ſolemn oath, either to place the king alive in his hands, or to kill him in caſe of reſiſtance. Theſe perſons, at the head of forty dragoons, entered Warſaw in diſguiſe, attacked and ſeized the king, and after having wounded him in the head with a ſabre, dragged him through the ſtreets, and carried him out of the city. After a while the conſpirators were alarmed at what they had done, and they all, except one, took advantage of the darkneſs of night to make their eſcape, and at day-break the king found himſelf alone with a perſon named Koſiuſki, and both of them on foot. Taking advantage of the perplexity in which he ſaw this man was involved, the king repreſented to him in ſuch colours the atrocity of the attempt, to which he added the promiſes of pardon and even reward, that he entirely gained him over, and they proceeded together to a mill. From thence the king wrote the following letter. "Par une eſpèce de miracle je ſuis ſauvé des mains des aſſaſſins. Je ſuis ici au petit moulin de Mariemont. Venez au plutôt me tirer d'ici. Je ſuis bleſſé, mais pas fort." He was accordingly conducted back to Warſaw, and received amidſt the joyful acclamations of the people.

Staniſlaus, though retaining his crown, was unable to quiet or direct the diſtractions of the country: nor could he make any effectual oppoſition to that truly infamous partition of a large portion of Poland between the plunderers of Ruſſia, Pruſſia, and Auſtria, which took place in 1773, and which may be regarded as the firſt act of thoſe open violations of every principle of national juſtice, which have ſo peculiarly ſtigmatized the times in which we live. The ſame powers enforced alterations in the Poliſh conſtitution, calculated to perpetuate its weakneſs, and which were in vain oppoſed by Staniſlaus and the beſt patriots of the country. In 1789 he had an interview with Catharine, who deluded him with hopes of advantages for the Poles, which, of courſe, were never realized: and in 1792, the armies of Ruſſia and Pruſſia entered Poland, deſtroyed the conſtitution which had been formed by the people, and completed that diviſion of its territories which expunged its name from the map of Europe. In 1795 Staniſlaus was obliged, by order of the empreſs Catharine, to reſign, and abdicate the crown which ſhe had hitherto allowed him to wear, and he retired to Grodno, contented to live a penſioner on her bounty. On the acceſſion of Paul, Staniſlaus was treated with great reſpect. He died at Peterſburg in 1798, beloved and eſteemed for his qualities in private ſociety.

Stanislaus, *Order of St.*, was inſtituted by Staniſlaus, king of Poland, in the year 1765. The badge of the order is a gold croſs, enamelled red; on the centre a medallion; on this the image of St. Staniſlaus, enamelled in proper colours; on the reverſe, the letters SS in a cypher. It is worn ſcarfwiſe, pendent to a broad watered ribband, edged with white. The ſtar of the order is ſilver, in the centre of which is a cypher of three letters, *viz.* S.A.R. ſignifying Staniſlaus Auguſtus Rex; within, the following motto, Præmiando incitat.

STANISLOW, in *Geography*, a town of Auſtrian Poland, in Galicia; 66 miles S.S.E. of Lemberg.

STANITZ, a town of Bohemia, in the circle of Chrudim; 13 miles N. of Chrudim.—Alſo, a town of Moravia, in the circle of Brunn; 18 miles S.E. of Brunn.

STANK, is a dam made with pile-planks, or otherwiſe, to pen water.

STANKAU, in *Geography*, a town of Bohemia, in the circle of Pilſen; 9 miles N.N.E. of Pilſen.

STANLEY, Thomas, in *Biography*, born at Cumberlow-Green, in Hertfordſhire, was the ſon of ſir Thomas Stanley, knight. He received his early education at home, under Edward Fairfax, the tranſlator of Taſſo's Jeruſalem, and was admitted a gentleman-commoner of Pembroke-hall, Cambridge, in 1639. Having taken his degree of M.A. at that univerſity, he went abroad, but returning during the civil war, he took up his reſidence in the Middle Temple. He there purſued his ſtudies with much eagerneſs, and in 1651 publiſhed a volume of original poems, and a number of tranſlations in verſe from the ancient and modern languages. Turning his attention to graver topics, in 1655 he publiſhed the firſt volume of the work by which he is chiefly known, "The Hiſtory of Philoſophy; containing the Lives, Opinions, Actions, and Diſcourſes of the Philoſophers of every Sect." This was followed by three other volumes; they were afterwards republiſhed in one volume folio; and in 1743, a quarto edition was given to the public. After the favourable reception which this work met with, the author publiſhed an edition of Æſchylus, which was publiſhed in London in 1663, the text of which was copied into De Pauw's edition of 1745. He died in London, April 12, 1678, leaving behind him farther monuments of his induſtry and erudition, in manuſcript, conſiſting of "Commentaries on Æſchylus," in 8 vols. fol.: "Adverſaria; or Remarks on Paſſages in various ancient Authors:" "Prelections on the Characters of Theophraſtus:" and a Latin treatiſe on the firſt-fruits and tenths of the ſpoils mentioned in the Epiſtle to the Hebrews. He had been married to a Northamptonſhire lady, co-heireſs to a good eſtate, and he left a ſon, who publiſhed, at an early age, a tranſlation of Ælian's "Various Hiſtories."

Stanley, John, bachelor in muſic, was born in 1713. At two years old he totally loſt his ſight, by falling on a marble hearth with a china baſon in his hand. At the age of ſeven he firſt began to learn muſic, as an art that was likely to amuſe him, but without his friends ſuppoſing it poſſible for him, circumſtanced as he was, to make it his profeſſion. His firſt maſter was Reading, a ſcholar of Dr. Blow, and organiſt of Hackney. But his father finding that he not only received great pleaſure from muſic, but had made a rapid progreſs, placed him with Dr. Greene, under whom he ſtudied with great diligence, and a ſucceſs that was aſtoniſhing. At eleven years of age he obtained the place of organiſt of All-hallows, Bread-ſtreet, and in 1726, at the age of thirteen, was elected organiſt of St. Andrew's, Holborn, in preference to a great number of candidates. In 1734, the benchers of the honourable ſociety of the Inner Temple elected him one of their organiſts. Theſe two places he retained till the time of his death. Few profeſſors have ſpent a more active life in every branch of his art than this extraordinary muſician; having been not only a moſt neat, pleaſing, and accurate performer, but a natural and agreeable compoſer, and an intelligent inſtructor. He was the conductor and ſoul of the Swan and Caſtle concerts in the city, as long as they ſubſiſted. Upon the death of Handel, he and Mr. Smith undertook to ſuperintend the performance of oratorios during Lent; and after Mr. Smith retired, he carried them on, in conjunction with Mr. Linley, till within two years of his death, in 1786. This ingenious and worthy profeſſor, whoſe blindneſs excited the pity, and performance the admiration, of the public for ſo many years, will be long lamented by his ſurviving friends; for they have loſt in him, excluſive of his muſical talents, a moſt intelligent and agreeable companion, who contributed to the pleaſures of ſociety as much by his converſation in private, as by his profeſſional merit in public. He was ſucceeded in his office as maſter of the king's band, by Mr., afterwards ſir William Parſons. See Paradis, *Mademoiſelle.*

STANLEY, in *Geography*, a townſhip in the pariſh of Wakefield, Yorkſhire. See WAKEFIELD.

STANMORE, GREAT, a pariſh in the hundred of Gore, and county of Middleſex, England, is 10 miles N.W. from London. It compriſes 1400 acres of land, the greater part of which is occupied as meadow and paſture, but about 250 acres ſtill remain in common. From the number of Roman antiquities found within this pariſh, it is conjectured by Camden, Stukeley, and Reynolds, that the ſtation called Sulloniacæ was at Brockley-hill. During the Anglo-Roman dynaſty, this part of Middleſex, and a great part of Hertfordſhire, were covered with woods: indeed, at the time of compiling the Domeſday ſurvey, it appears to have been chiefly foreſt. Fitz-Stevens, who wrote about 1170, ſays that an immenſe foreſt extends itſelf to the north of London, "and is full of the lairs and coverts of beaſts and game." The village of Stanmore is of conſiderable extent, and conſiſts chiefly of houſes erected on the ſides of the great road from London to St. Albans. There are ſome handſome manſions and villas within the pariſh; the chief of which is Stanmore-houſe, the elegant ſeat of the counteſs of Aylesford. The houſe is ſeated in an extenſive park, diſtinguiſhed for its varied ſurface and fine woods. A villa called the Grove, the reſidence of Charles Poole, eſq. was poſſeſſed by Aaron Capadoce in 1802, who died here in that year, at the age of 105.

The preſent church of Stanmore was completed in 1632, at the ſole expence of ſir John Wolſtenholme, knt. It is built of brick, and among other monuments is one by Nicholas Stone, commemorating the builder of the church. It contains a ſtatue of the deceaſed, finely executed, and coſt 200*l.* (See Walpole's Anecdotes of Painting.) In the pariſh of Stanmore-Parva is Canons, an ancient and celebrated ſeat of the Brydges family. This eſtate was rendered noted by James Brydges, duke of Chandos, who was paymaſter of the forces to queen Anne, and who, having accumulated great wealth, reſolved to build two magnificent houſes, to ſurpaſs any of the ducal reſidences in England. One was commenced in Cavendiſh-ſquare, London, but never finiſhed; the other at Canons. Three architects were employed, Gibbs, James, and Shepherd; and Vertue deſcribes the houſe as "a noble ſquare pile, all of ſtone;" ornamented with ſtatues, buſts, paintings, &c. Italian artiſts were employed to ſtucco and paint the walls and cielings, and a profuſion of marble was uſed in pillars, floors, &c. In the erection and decoration of this noble manſion, and in planting the ground, it is related that not leſs than 250,000*l.* were expended. Correſponding with the building were the domeſtic eſtabliſhment and ſtyle of living within the houſe: all was grandeur and oſtentation. The duke dined in public, and was attended by a band of muſic and a military guard. This parade excited the envy and ſatirical animadverſions of Pope and ſome other poets. In Pope's ſatire on Falſe Taſte, the character of Timon is ſuppoſed to be intended for the duke. The ſplendid manſion juſt mentioned was taken down, and the materials ſold by auction, in 1747; and a ſmall but neat villa was afterwards built by Mr. Hallet, and which is now the property and reſidence of ſir Thomas Plumer. Beauties of England, vol. x. pt. 4. Middleſex. By J. N. Brewer, 1816.

STANNARIES, STANNARIA, the mines and works where tin is dug and purified: as in Cornwall, Devonſhire, &c. There are four courts of the ſtannaries in Devonſhire, and as many in Cornwall, for the adminiſtration of juſtice among the tinners. See *Stannary*-COURTS.

STANNEL, in *Ornithology*, an Engliſh name of a ſpecies of hawk, more commonly known by the names of the *keſtrel*, or the *windhover*; and called by Latin authors *tinnunculus* and *cenchris*.

STANNER-WORT, in *Agriculture*, the common name of a troubleſome weed in arable as well as graſs-lands. See RAG-WORT.

STANNUM, TIN. See TIN.

STANOVAIA, in *Geography*, a fortreſs of Ruſſia, in the government of Toboliſk; 8 miles S.W. of Iſchim.

STANOVITZKOI, a town of Ruſſia, in the government of Novgorod; 48 miles N.W. of Tcherapovetz.

STANSTEAD, a townſhip of Lower Canada, bounded W. by lake Memphramagog, and S. by Vermont: ſettled by about 750 inhabitants, a promiſcuous emigration from various parts of the United States.

STANSTED, a town of Virginia; 5 miles N. of Falmouth.

STANTONS, a town of North Carolina; 8 miles W. of Guildford.

STANTZ, a town of Switzerland, in the canton of Unterwalden, of which it was formerly the capital, on the lake of Lucerne; 8 miles S.E. of Lucerne. N. lat. 46° 51′. E. long. 8° 10′.—Alſo, a river of Stiria, which runs into the Muehr, 20 miles E.S.E. of Luttenberg.

STANZA, in *Poetry*, a certain ſtated number of grave verſes, containing ſome perfect ſenſe, terminated with a reſt or pauſe.

The word is Italian, and literally ſignifies a ſtand or ſtation, becauſe of the pauſe to be made at the end of each ſtanza, or complete ſenſe.

What the *couplet* is in ſongs, and the *ſtrophe* in odes, the *ſtanza* is in the great and graver pieces, as epic poems, &c. Indeed, the Italians ſcarcely write any poems but they divide them into ſtanzas. There are ſtanzas of four, ſix, eight, ten, twelve, and fourteen verſes, and ſometimes of an uneven number of verſes, as five, ſeven, &c. But theſe laſt are ſomewhat more difficult to execute, by reaſon of the three verſes to one rhyme. The French lay it down as a rule, that if the firſt ſtanza begin with a maſculine or feminine verſe, the ſecond is to begin and end with the ſame.

Every ſtanza ought not only to contain a perfect ſenſe, but to be terminated with ſome lively and ingenious thought, or ſome juſt and pertinent reflection.

Stanzas were firſt introduced from the Italian into the French poetry about the year 1580, and thence they were transferred into the Engliſh.

The uſe of ſtanzas in tragedy, or comedy, is condemned by all the beſt critics; for though we ſpeak verſe on the ſtage, it is ſtill preſumed we are ſpeaking proſe. Stanzas ſhew a degree of ingenuity on the part of the poet, which has nothing of nature in it on the part of the actor. Add to this, that ſtanzas are not fit to expreſs every thing: wrath, threatening, &c. ſit very ill on a regular ſtanza; though irreſolution, reveries, and every thing that leads the actor to think on what he is to reſolve, agree well enough with the unequal cadence of the ſtanza.

STANZIONE, CAVALIERE MASSIMO, in *Biography*, was born at Naples in 1585, and was a diſciple of G.B. Caraciolo: he alſo received inſtructions in freſco painting from Beliſario Coſenzio, one of the moſt eminent artiſts of his time, and indeed ſeems to have been exceedingly ſtudious of the works of all the great painters of his day. He viſited Rome, and in ſtudying the works of Annibal Caracci, became intimate with Guido Rheni, into whoſe ſtyle he fell with ſo much ſucceſs, that he obtained the name of *Il Guido Rheni di Napoli*.

It was in his native city that he principally exerted his ability in original productions, and was ranked among its ableſt artiſts. Spagnoletto became jealous of him, and is ſaid by Lanzi to have been guilty of a groſs piece of perfidy to deſtroy the picture he had painted in competition with his Deſcent from the Croſs, for the Certoſa. The ſubject of his picture was Chriſt with the Maries, which having ſomewhat changed in tone, and become darker, Spagnoletto perſuaded the monks to permit him to clean it; when he uſed ſome noxious preparation, which nearly deſtroyed the work. Upon application to Stanzione to remedy the miſchief, he refuſed, declaring it ſhould remain as it was, that the author of ſo diſgraceful a procedure might reap the juſt fruits of his perfidy.

Among the conſiderable works executed by Stanzione at Naples, are the cielings of the churches of St. Paolo and del Geſu Novo, and a large picture at the Certoſa, repreſenting St. Bruno preſenting the regulations of his order to his monks. The ſmall cabinet pictures by him are numerous, and much eſteemed. He died at the age of 71, in the year 1656.

STAPEDIUS, or STAPIDÆUS, or *Stapidis Muſculus*, in *Anatomy*, the ſmalleſt muſcle in the body, ſituated in the tympanum of the ear. See EAR.

STAPELBURG, in *Geography*, a town of Germany, in the county of Wernigerode; 6 miles W. of Wernigerode.

STAPELIA, in *Botany*, an extenſive and very ſingular genus of African plants, ſo named by Linnæus, in honour of Dr. John Bodæus a Stapel, the laborious and learned Dutch editor of Theophraſtus. His edition of this ancient author, publiſhed in folio at Amſterdam, in 1644, is the beſt which has appeared.—Linn. Gen. 121. Schreb. 169. Willd. Sp. Pl. v. 1. 1277. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 84. Brown Tr. of the Wernerian Society, v. 1. 23. Juſſ. 146. Lamarck Illuſtr. t. 178.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ. *Aſclepiadeæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, ſmall, in five acute ſegments, permanent. *Cor.* of one petal, large, thick, divided more than half way into five broad, flat, pointed ſegments, ſometimes with intermediate teeth. Nectary (or Crown of the ſtamens) double; the outer in five ſegments or leaves, various in different ſpecies; inner of five leaves, alternate with the outer, undivided, ſometimes obſolete; all much ſhorter than the petal. *Stam.* Filaments five, flat, ſhort, more or leſs connected; anthers ſimple at the point; "maſſes of pollen attached by their baſe, cartilaginous and pellucid at one margin." *Br. Piſt.* Germens two, ovate, flat on the inner ſide; ſtyles none; common ſtigma pointleſs. *Peric.* Follicles two, nearly cylindrical, ſmooth, taper-pointed. *Seeds* numerous, imbricated, compreſſed, crowned with fine hairs.

Eſſ. Ch. Corolla of one petal, five-cleft. Nectary a double ſtar, covering the organs of impregnation. Common ſtigma pointleſs. Follicles two, ſmooth. Seeds comoſe.

Such is the Linnæan genus of *Stapelia*, preſerved entire by the late Mr. Dryander, in Ait. Hort. Kew., though Mr. Brown has ſeparated ſome genera from it. (See HUERNIA and PIARANTHUS.) We have already, under thoſe articles, ventured to expreſs an opinion that the original genus, on account of its very diſtinct habit, and the varieties of ſtructure in its nectary or crown, might beſt remain undiſturbed. We ſhall therefore conſider it under that point of view, giving examples of its various ſections. Linnæus has, even in the fourteenth edition of Syſt. Veg., but five *Stapeliæ*; Willdenow has forty-nine, moſtly adopted from Mr. Maſſon's rich and ſplendid illuſtration of this genus, publiſhed in 1796, with forty-one coloured folio plates. As this able collector ſent moſt of his diſcoveries to Kew, forty-four ſpecies appear in Mr. Aiton's work. They are all natives of the deſerts of Southern Africa, except three found by Forſkall in Arabia Felix, and one by Roxburgh in India. Their habit is extremely ſucculent, toothed, angular, and gibbous, without *leaves*. *Flowers* lateral, ſtalked, various in ſize, parti-coloured, generally of a dark and ſpeckled hue, often remarkable for an extraordinary fetor, reſembling carrion, rotten cheeſe, corrupted water, or ſuch delectable odours, and grateful perhaps to the Hottentots, to whoſe country theſe flowers belong. The *Stapeliæ* are eaſily cultivated in pots, in a dry ſtove, with very ſparing ſupplies of water, and as much ſun as our ſkies will afford. They bloſſom pretty freely, at various ſeaſons, and if their odour can be tolerated, their beauty will amply repay the moderate care they require.

Section 1. *Corolla ſimple, five-cleft, its edges hairy.* Twenty ſpecies.

S. *ciliata.* Fringed Buff Stapelia. Willd. n. 1. Ait. n. 1. Maſſon Stap. 9. t. 1. Thunb. Prodr. 46.—Stem procumbent. Teeth of the branches ſpreading. Surface of the corolla papillary; its margin fringed; ſegments ovate, acute.—Native of very dry ſituations at the Cape of Good Hope, below the hill called *Bockland Berg*. It flowers in our gardens from October to December. The *ſtem* is branched, procumbent, taking root here and there, with ſhort, erect *branches*, ſtained with brown, intermixed with a leſs glaucous green than in moſt other ſpecies; its length about a foot. The teeth of the branches are unuſually large and ſpreading, ſomewhat unequal and irregular. *Flowers* ſolitary, near three inches wide, buff-coloured; violet in the centre. Hairs of their fringe minutely club-ſhaped.

S. *hirſuta.* Hairy Stapelia, or Carrion Flower. Linn. Sp. Pl. 316. Willd. n. 3. Ait. n. 3. Jacq. Miſc. v. 1. 28. t. 3. (Aſclepias africana aizoides, flore pulchrè fimbriato; Commel. Rar. 19. t. 19.)—Branches aſcending, quadrangular, with erect teeth; flowering at the baſe. Corolla hairy at the margin and centre; ſegments ovate, acute, tranſverſely corrugated.—Native of the Cape. Introduced very early from thence, by the Dutch, into the gardens of Europe, where it has ever ſince been preſerved. The *flower* is large and handſome, of a dark chocolate crimſon, ſtreaked acroſs with yellow; the marginal fringe reſembling grey fur. Its ſcent is ſo like carrion, that fleſh-flies lay their eggs upon it, and the maggots are ſtarved for want of their proper food. Sir John Hill aſſerted, in an expreſs diſſertation, that theſe flies are a peculiar ſpecies, whoſe maggots feed on the flower. For which falſehood he is ſtigmatized by the great entomologiſt Fabricius, as "*damnandæ memoriæ Johannes Hill.*"

S. *ſororia*, Maſſon, t. 39; *grandiflora*, t. 11; *ambigua*, t. 12; and *Aſterias*, t. 14; are nearly related to *hirſuta*, in the ſize and general aſpect of their flowers, but all ſufficiently diſtinct.

S. *pulvinata.* Cuſhion-flowered Stapelia. Maſſon Stap. 13. t. 13. Willd. n. 7. Ait. n. 6. Curt. Mag. t. 1240.—Stem procumbent. Branches quadrangular, with erect teeth; flowering at the baſe. Corolla hairy at the margin; its rounded ſegments ſhorter than the diameter of the tumid ſhaggy centre.—Native of the Cape, in buſhy places at *Camies berg*. *Maſſon.* The Dutch inhabitants call this ſpecies the Arabian Roſe, notwithſtanding its fetor. For ſize and beauty it is indeed conſpicuous, and though akin to *hirſuta*, and to the other ſpecies we have juſt named, is diſtinguiſhed by the very tumid, ſhaggy, cuſhion-like centre of the *flower*, and the ſhort, rounded ſegments of the limb, each tipped with a ſharp point, of a different colour from its diſk.

S. *divaricata.* Straddling Stapelia. Maſſon Stap. 17. t. 22. Willd. n. 10. Ait. n. 9. Curt. Mag. t. 1007.—Branches bluntly quadrangular, tapering, ſpreading. Corolla very even; its ſegments lanceolate, pointed; revolute and diſtantly fringed at the margin.—Sent by Mr. Maſſon, from the Cape, in 1793. The habit is ſlender, lax, and ſpreading. *Flowers* ſmaller than any of the foregoing, being but two inches wide, of a deep fleſh-colour, poliſhed, peculiarly ſmooth; their ſegments narrow, and ſo much reflexed, that the hairs on their edges may eaſily eſcape notice.

S. *parviflora.* Small-flowered Stapelia. Maſſon Stap. 22. t. 35. Willd. n. 17. Ait. n. 16.—Branches acutely quadrangular, with recurved teeth; flowering in the upper part. Segments of the corolla lanceolate, fringed, ſhorter than the flower-ſtalk.—Native of buſhy parts of Namaqua land. The branched *ſtems* are erect and ſtout, bright green, with large, compreſſed, hooked teeth. *Flowers* not half an inch broad, yellow, hairy, on deflexed purple *ſtalks*, ſcarcely an inch in length.

S. *glanduliflora.* Glandular-flowered Stapelia. Maſſon Stap. 16. t. 19. Ait. n. 18. Sm. Exot. Bot. v. 2. 23. t. 71. (S. glandulifera; Willd. n. 20.)—Branches quadrangular, with upright teeth. Segments of the corolla ovate, acute, covered with club-ſhaped glands, and ſhorter than the flower-ſtalk.—Found in the deſerts about *Nord Olifant's* river, by Mr. Maſſon, who ſent it to Kew in 1795. It flowers there late in autumn. The *ſtems* are green, erect, ſomewhat downy at the edges. *Flowers* above an inch broad, tawny or yellowiſh, clothed with erect club-ſhaped glands, of a very ſingular appearance. Crown of the *ſtamens* orange and black.

Section 2. *Corolla ſimply five-cleft, ſmooth-edged.* Twenty-two ſpecies, to which ſome are added in Hort. Kew. and Curt. Mag.

S. *pedunculata.* Long-ſtalked Stapelia. Maſſon Stap. 17. t. 21. Willd. n. 21. Ait. n. 19. Curt. Mag. t. 793.—Branches bluntly angular, toothed at the top. Segments of the corolla lanceolate, acute, with tufts of pendulous glands at the baſe. Flower-ſtalks twice as long as the branches.—Native of dry places at *Camies berg. Maſſon.* The *branches* are glaucous, tumid, with blunt, often obliterated angles, rather notched than toothed, except at the end. *Flower ſtalks* five or ſix inches long. *Flowers* an inch and half, or two inches, wide, with narrow convex ſegments, of a more or leſs deep or variegated brown, accompanied at the baſe by pendulous tufts of trembling black glands. The centre of the *flower* is alſo black.

S. *Gordoni.* Gordon's Stapelia. Maſſon Stap. 24. t. 40. Willd. n. 23.—Corolla orbicular, very ſlightly five-cleft. Stem branched, round, with copious ſpinous tubercles.—Gathered in *Groot Namaqua Land,* near Orange river, by Mr. Gordon, from whom Mr. Maſſon received a drawing of this very ſingular ſpecies, it being the only one of the genus he had not himſelf ſeen and examined. The *ſtem* is repreſented erect, branched, a foot high, green, very thick and obtuſe, beſet all over with blunt tubercles, each bearing a prominent thorn. *Flowers* above two inches wide, of a pale nearly even brown, very ſmooth, convex, with five very ſhallow acute lobes, and a little blackiſh crown in the middle. The *ſtalk* is hardly an inch long.

S. *pilifera.* Hairy-tubercled Stapelia. Linn. Suppl. 171. Willd. n. 24. Ait. n. 21. Maſſon Stap. 17. t. 23.—Branches erect, round, tumid, with copious tubercles, each tipped with a briſtle. Segments of the corolla ovate, pointed, ſmooth. Flowers ſeſſile, ſcattered.—Native of very dry hills, in the deſerts at the Cape of Good Hope. The Hottentots are ſaid to eat it, knowing it by the name of *Guaap.* The habit of the plant is very like the laſt, only the tubercles are ſmaller in proportion, and bear briſtles inſtead of thorns. The *flowers* are ſmall, half an inch broad, ſmooth, of a dark purpliſh-brown, with a black and yellow crown, ſurrounded by a red circle. This ſpecies confirms the genus of the laſt, if there could be any doubt on that ſubject.

S. *articulata.* Jointed Stapelia. Maſſon Stap. 20. t. 30. Willd. n. 26. Ait. n. 22.—Branches ſpreading, round, teſſellated with pointed tubercles. Flowers nearly ſeſſile; their ſegments triangular, papillary.—Native of the country of *Roggeveldt,* at the Cape of Good Hope. The Hottentots eat it raw; the Dutch ſettlers pickle it with vinegar. This is of a glaucous, often reddiſh, hue, and ſingularly teſſellated, growing in a proliferous ſtraggling form; its ſtructure akin to the two laſt. *Flowers* very ſmall; their parts not clearly intelligible from Maſſon's figure, nor have we ſeen a recent ſpecimen. They are ſcattered about the toothed ſummits of the branches.

S. *mammillaris.* Prickly Stapelia. Linn. Mant. 2. 216. Willd. n. 27. Ait. n. 23. (S. aphyllos, ad nodos mammillaris, floſculo rubello, ſiliquis pendulis; Burm. Afric. 27. t. 11.)—Branches erect, roundiſh, with copious ſpinous tubercles. Flowers ſtalked; their ſegments lanceolate, ſmooth.—Native of the Cape, from whence it was ſent to Kew, by Mr. Maſſon, and having flowered there, proves very diſtinct from the laſt, to which he ſuſpects, in his work, it might belong. The *tubercles* are prominent, and their *ſpines* very ſtout, even more ſo than in *S. Gordoni,* which this ſpecies nearly equals in ſtature. The *flowers* however are much ſmaller, and totally different in the form of their ſegments.

S. *pulla.* Black-flowered Stapelia. Maſſon Stap. 21. t. 31. Willd. n. 30. Ait. n. 26.—Branches imperfectly hexagonal, erect, with ſpreading ſpinous teeth. Segments of the corolla lanceolate, revolute, ſmooth.—Native of the hot ſandy deſerts called *Karròo,* at the Cape of Good Hope. Brought to Kew by Mr. Maſſon, in 1774. This is ſomewhat related to the laſt, being, though leſs tuberculated, and more angular, furniſhed with ſimilar ſpines. The *flowers* alſo ſeem ſimilarly formed. They grow, ſeveral together, on ſhort aggregate ſtalks, and are pale externally, but almoſt black on the upper ſurface of their narrow, taper, almoſt erect, ſegments.

S. *adſcendens.* Eaſt Indian Stapelia. Roxb. Corom. v. 1. 28. t. 30. Willd. n. 31. (Caralluma; Brown Tr. of the Wern. Soc. v. 1. 25.)—Branches quadrangular, aſcending, toothed, flowering about the ſummit. Segments of the corolla ovato-lanceolate, pointed, revolute, ſmooth.—Found among buſhes, on high dry barren ground in the Eaſt Indies, flowering in the wet ſeaſon. The Telingas, according to Dr. Roxburgh, call it *Car-allum,* and eat the young tender branches raw, though they are bitter and ſalt to the taſte. The *ſtems* are perennial, ſlender, a foot or two high, branched, their angles beſet with aſcending teeth. *Flowers* near an inch in diameter, ſcattered, on ſhort ſtalks, towards the ends of the branches. Segments of the *corolla* green in the lower half; dark purple in the other part; pale beneath. We can form no idea of the ſtructure of the *crown,* or neighbouring parts, from the figure, nor has Dr. Roxburgh ventured to explain them. Mr. Brown deſcribes the *crown* as of ten leaflets, in a ſimple ſeries;

five of them oppoſite to the anthers, and undivided; the laſt deeply divided, awl-ſhaped. With much reſpect for his opinion, we think the plant ought not to be ſeparated from *Stapelia*, and therefore we need ſay nothing of his generic name.

S. *incarnata.* Fleſh-coloured Stapelia. Linn. Suppl. 171. Willd. n. 33. Ait. n. 27. Maſſon Stap. 22. t. 34. (Euphorbium erectum, quadrangulare, ſpinoſum, ramis lateralibus rotundis folioſis; Burm. Afric. 15. t. 7. f. 1.)—Branches quadrangular, erect, toothed, flowering about the ſummit. Segments of the corolla lanceolate, flat, pointleſs, ſmooth.—Found by Thunberg and Maſſon, in dry ſandy fields at the Cape. About a foot high, glaucous, much ſtouter than the laſt. *Flowers* numerous, nearly ſeſſile, ſcattered about the upper part of each branch, each half an inch broad, pale pink or white. The Hottentots are ſaid to eat the branches.

S. *punctata.* Purple-dotted Stapelia. Maſſon Stap. 18. t. 24. Willd. n. 34. Ait. n. 28.—Stem proliferous, decumbent, with oblong, ſomewhat quadrangular, toothed joints. Corolla bell-ſhaped, with lanceolate acute ſegments; papillary on the upper ſurface.—Native of the *Namaqua lands*, in Southern Africa. Sent to Kew in 1795, where it flowers moſt part of the autumn. This is one of a tribe, of which Mr. Maſſon has deſcribed ſeveral more ſpecies, whoſe *ſtems* are compoſed of oblong or elliptical, proliferous joints, or branches, and whoſe *flowers*, ſupported by longiſh *ſtalks*, have lanceolate acute ſegments, dotted or glandular all over their upper ſurface. In the preſent inſtance the *corolla*, about an inch in diameter, has a bell-ſhaped tube, externally of a blueiſh-white. The upper ſide is pink, with purple dots. The *flower-ſtalks*, near two inches long, grow three or four together, and are of the ſame pink hue as the corolla

S. *geminata*, Maſſon t. 25, and *decora*, t. 26, are, in habit and general character, allied to the laſt.

S. *picta.* Painted Stapelia. Sims in Curt. Mag. t. 1169. Ait. n. 34. (S. variegata; Jacq. Miſc. v. 1. 27. t. 4.)—Branches ſimple, aſcending, quadrangular, with ſpreading teeth. Segments of the corolla ovate, pointed, corrugated; the annular centre very rugged. Five leaflets of the crown cloven.—Native of the Cape of Good Hope, from whence Meſſrs. Loddiges are ſaid to have introduced it into the Engliſh collections. The ſtructure of the nectary however induces us to believe, with Dr. Sims, it is what Jacquin has figured as *S. variegata* of Linnæus, hereafter mentioned. This belongs, with the real *variegata*, to no leſs diſtinct a tribe of ſpecies than the laſt. Their *ſtems*, compoſed of numerous ſimple erect *branches*, have a tufted habit; their colour is leſs glaucous than in moſt others; the teeth of their branches are numerous, and ſtrongly marked, ſpreading in four rows. *Flowers* about two inches wide, on deflexed ſolitary *ſtalks*, yellow, either tranſverſely ſtreaked or dotted with a chocolate-brown; their ſegments broad, rugged or warty. Crown of the *ſtamens* various in the different ſpecies. The colouring of the preſent flower is darker, and more blotched, than uſual.

S. *verrucoſa.* Warty-flowered Stapelia. Maſſon Stap. 11. t. 8. Willd. n. 39. Ait. n. 35. Curt. Mag. t. 786?—Branches ſimple, aſcending, bluntly quadrangular, with ſpreading teeth. Segments of the corolla ovate, pointed, warty; the centre concave, with a rough pentagonal elevation.—Found in dry ground at the Cape. Akin to the laſt, but the *corolla* is warty, or tuberculated, not tranſverſely corrugated. We cannot but have ſome doubts concerning the ſynonym of the Botanical Magazine, as the repreſentation there of the crown of the *flower* is not reconcileable to Mr. Maſſon's figure. One or the other muſt be incorrect. In the *branches* we ſee no important difference.

S. *irrorata*, Maſſon t. 9, is one of the ſame tribe, and perhaps nearer the plant of the Botanical Magazine.

S. *variegata.* Variegated Stapelia. Linn. Sp. Pl. 316. Willd. n. 42. Ait n. 37. Curt. Mag. t. 26. (Fritillaria craſſa, promontorii Bonæ Spei; Stapel. Theophr. 335.)—Stem branched upwards, quadrangular, with ſpreading teeth. Segments of the corolla ovate, pointed, corrugated; the annular centre concave, rugged. Leaflets of the crown all undivided.—Native of the Cape, from whence it was early brought to Europe. This is moſt akin to *S. picta;* but if the obſervations of our friend Dr. Sims be, as uſual, correct, the leaflets of the *crown*, or *nectary*, being all undivided in the true *variegata*, eſſentially diſtinguiſh it. This *flower* ſmells like rotten cheeſe. It is prettily ſpotted with brown on a yellow ground. We dare not rely on all the old ſynonyms, the crown not being accurately expreſſed; eſpecially as there are ſeveral ſpecies, ſo eaſily to be confounded with the preſent, which may have been cultivated, without being well diſtinguiſhed.

S. *bufonis*, Curt. Mag. t. 1676, is one of theſe uncertain ſpecies, nearly akin to the *picta.* They require to be all compared in a living ſtate, particularly with regard to the ſtructure of the *crown.*

Section 3. *Corolla with five intermediate teeth.* Six ſpecies, to which one is added in Hort. Kew. This ſection comprehends Mr. Brown's genus HUERNIA. See that article.

S. *campanulata.* Bell-ſhaped Stapelia. Maſſon Stap. 11. t. 6. Willd. n. 43. Ait. n. 38. Curt. Mag. t. 1227, and t. 1661!—Corolla bell-ſhaped, with ten teeth, rough; its tube internally bearded. Branches with four compreſſed toothed angles.—Native of dry ground at the Cape, from whence ſeveral collectors have received living plants. The *branches* are thick, aſcending, ſomewhat tufted, with four, or more, very prominent, compreſſed angles, beſet with large, acute, compreſſed, projecting teeth. *Flowers* two inches wide, with a perfectly bell-ſhaped tube, which is lined, and almoſt filled up, with converging, glandular, purple hairs; limb in five pointed ſhallow lobes, with as many very ſmall intermediate ones, its inner ſurface cream-coloured or buff, dotted with purple. We cannot account for this ſpecies being given a ſecond time in the Botanical Magazine without any reference to the former figure, which beſt agrees with Mr. Maſſon's, and with the ſpecimens we have ſeen.

S. *reticulata.* Netted Stapelia. Maſſon Stap. 9. t. 2. Willd. n. 48. Ait. n. 43. Curt. Mag. t. 1662.—Corolla with ten teeth; its tube internally bearded, and ſurrounded with a tumid ring. Branches with five compreſſed angles, beſet with hooked teeth.—Found in hollows of rocks, near north *Olifant's* river, at the Cape. The numerous, rather hooked teeth of the *branches*, differ ſomewhat from the laſt. Maſſon's figure of the *flower* is more ſtriking, and more faithful, than that of the Magazine. The *corolla*, beautifully variegated with crimſon and dark purple, is marked with a kind of net-work. The ring round its mouth, or tube, is ſingularly tumid; the latter is filled with purple hairs, as in *S. campanulata.*

S. *lentiginoſa.* Freckled Stapelia. Sims in Curt. Mag. t. 506. Ait. n. 44.—Corolla with ten teeth; its tube bell-ſhaped, naked, ſurrounded with a tumid ring. Stems branched in the upper part, five-angled, with hooked teeth.

Brought by Mr. Maſſon from the Cape to Kew in 1795, though it does not occur in his work. The *flower* moſt agrees with his *guttata*, but the habit of the plant is very different.

Section 4. *Flowers not yet obſerved.* One ſpecies. *Willdenow.*

S. *clavata.* Club-ſhaped Stapelia. Willd. n. 49.—"Stem ſimple, thick, club-ſhaped, reticulated with obſcure warts, flowering at the ſummit."—Gathered by governor Patterſon, in ſandy fields beyond *Kopperberg*, at the Cape. He has delineated the fruit only in his travels, tab. 8, according to the German edition, cited by Willdenow.

We beg leave to obſerve that the two firſt ſections of the preſent genus are entirely artificial, the fringe of the *corolla* not leading to any natural affinities of ſpecies.

Stapelia, in *Gardening*, contains plants of the ſucculent perennial kind, of which the ſpecies cultivated are, the hairy ſtapelia (S. hirſuta); and the variegated ſtapelia (S. variegata).

Method of Culture.—Theſe ſorts of plants are readily increaſed by cuttings or ſlips of the young branches, which ſhould be expoſed a few days in a dry covered place to heal over the cut part, and be then planted in pots, filled with light, poor, dry, freſh, ſandy earth, with lime rubbiſh, plunging them in the tan-bed of the ſtove, where they ſoon ſtrike root. When they are well rooted, they may be removed into ſeparate pots, replunging them in the bed till freſh rooted, when they may be placed on the tops of the flues, or on the ſhelves in the hot-houſe. They are alſo capable of being preſerved in the greenhouſe. They have a fine effect in their leafleſs, protuberant, warted appearance, and the beauty of their flowers, which are large, ſtellated, variegated, ſpotted, and differently ſtriped.

STAPES, in *Anatomy*, one of the ſmall bones of the ear, exactly reſembling in ſhape the iron part of a ſtirrup. See Ear and Cranium.

STAPHISAGRIA, in *Botany* and *Gardening*. See Delphinium.

Staphisagria, in the *Materia Medica*. See Stavesacre.

STAPHYLÆA, in *Botany*, abridged by Linnæus from *Staphylodendrum* of Tournefort and of ancient authors, derived from σταϐυλη, *a bunch*, or *cluſter*, and δενδρον, *a tree*, becauſe the cluſtered fruit of this ſhrub reſembles a bunch of grapes in its mode of growth.—Linn. Gen. 148. Schreb. 198. Willd. Sp. Pl. v. 1. 1497. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 377. Prodr. Fl. Græc. Sibth. v. 1. 208. Ait. Hort. Kew. v. 2. 171. Purſh v. 1. 129. Juſſ. 377. Tournef. t. 386. Lamarck Dict. v. 7. 391. Illuſtr. t. 210. Gærtn. t. 69.—Claſs and order, *Pentandria Trigynia.* Nat. Ord. *Trihilatæ*, Linn. *Rhamni*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, five-cleft, concave, roundiſh, coloured, the ſize of the corolla. *Cor.* Petals five, oblong, erect, like the ſegments of the calyx. Nectary at the receptacle of the fructification, in the baſe of the flower, concave, urn-ſhaped. *Stam.* Filaments five, oblong, erect, the length of the calyx; anthers ſimple. *Piſt.* Germen ſuperior, thickiſh, three-cleft; ſtyles three, ſimple, a little longer than the ſtamens; ſtigmas obtuſe, contiguous. *Peric.* Capſules three, inflated, flaccid, united longitudinally by a ſuture, pointed at the tip, burſting inwardly. *Seeds* two, bony, globular, with an oblique point, and an orbicular excavation at the ſide of the orifice.

Obſ. In *S. pinnata* the germen, inſtead of being three-cleft, is moſtly bifid, and there are generally but two capſules.

Eſſ. Ch. Calyx inferior, in five ſegments. Petals five. Capſules inflated, joined together. Seeds two, globoſe, with a ſcar on one ſide.

1. S. *occidentalis.* Jamaica Bladder-nut. Willd. n. 1. Swartz Ind. Occ. v. 1. 566. (Arbor jamaicenſis fraxini alatis foliis, floribus pentapetalis corymboſis; Pluk. Alm. 45. t. 269. f. 1.)—Leaves doubly pinnate. Capſules triangular. Seeds ſolitary. Stem arboreous.—Native of fields in the mountainous parts of Jamaica, flowering in the ſpring and autumn. A *tree* from twenty to thirty feet in height, with a ſmooth *trunk*, and round, ſmoothiſh, ſhining *branches*. *Leaves* alternate, ſtalked; leaflets two or three pair, ovate, pointed, ſerrated, ſmooth, ſhining. *Stipulas* two, between each pair of leaflets, ſmall, incurved. *Flowers* in terminal, erect, lax cluſters, white, fragrant, three on each ſtalk. *Capſules* ſcarcely inflated.

2. S. *pinnata.* Bladder-nut Tree. Linn. Sp. Pl. 386. Engl. Bot. t. 1560. "Schmidt. Arb. t. 80."—Leaves pinnated. Styles and capſules but two.—Native of the ſouth of Europe; but of ſuch rare occurrence in this country as to be ſcarcely deemed indigenous, although it is admitted into the Britiſh Flora. It bloſſoms in May or June, and perfects fruit rather late in the autumn. *Stem* ſhrubby, five or ſix feet high, branched, ſmooth. *Leaves* unequally pinnate; leaflets five, oppoſite, ovate, ſerrated, acute. *Stipulas* large, membranous, browniſh. *Flowers* in terminal, compound, drooping cluſters, bell-ſhaped, pale yellow. *Bracteas* ſetaceous, membranous. *Capſules* two, rarely three, membranous, inflated, each containing two large, globular *ſeeds*, which when ripe are hard, light brown, and look as if varniſhed.

The general appearance of this ſhrub ſomewhat reſembles that of the common Aſh.

3. S. *trifolia.* Three-leaved Bladder-nut. Linn. Sp. Pl. 386. "Schmidt. Arb. t. 81."—Leaves ternate.—Native of dry hills, in rocky ſituations from New York to Upper Carolina, flowering in May and June. *Purſh.* *Stem* ſtouter than in the laſt ſpecies; the older *branches* grey; the younger green, ſmooth. *Leaves* three together, ovate, pointed, ſerrated, the terminal one largeſt. *Flowers* produced from the ſides of the branches, in longer cluſters, but on ſhorter ſtalks, of a clearer white, and ſomewhat larger than in the laſt.

Staphylæa, in *Gardening*, contains plants of the hardy, deciduous, flowering, ſhrubby kind, of which the ſpecies cultivated are, the five-leaved bladder-nut (S. pinnata); and the three-leaved bladder-nut (S. trifolia).

Method of Culture.—Theſe plants may be increaſed by ſeeds, ſuckers, layers, and cuttings. The ſeeds ſhould be ſown as ſoon as they become ripe, in the autumn, in a bed of common earth, to the depth of an inch: they ſhould be kept clear from weeds, and refreſhed in dry weather with water frequently. In the following autumn or ſpring, the large plants ſhould be removed into nurſery-rows, at two feet apart, and one foot diſtant in the rows, to remain till of ſufficient growth for the ſhrubbery. The ſuckers may be ſeparated and taken up in autumn, or early in the ſpring, with root-fibres to them, and planted in nurſery lines in the above manner. The layers may be put down from the young branches, being either ſlit or twiſted; and, when properly rooted in the following autumn, be planted out in the nurſery as above. The cuttings ſhould be made from the lower parts of the young ſhoots of the preceding year, planting them in a ſhady border in the autumn, and watering them frequently during the ſpring and ſummer, when the weather is dry; and when well rooted, in the autumn following, planting them out in the nurſery-rows as above, or where they are to remain. They afford ornament and variety in the ſhrubbery parts of pleaſure-grounds, as well as in ſome other parts, by their long pendulous bunches of flowers, and bladder-ſhaped capſules, which have a ſingular appearance and effect in the autumnal ſeaſon.

STAPHYLE, a word uſed by the old Greek writers, ſometimes to expreſs a grape, and ſometimes a diſorder of the uvula, which conſiſts in an extenuation of its ſuperior part, and a tumour of the inferior, whence it hangs down in the ſhape of a grape. The uvula, or gargareon, is alſo thus called by ſome writers.

STAPHYLEPARTES, the name of a chirurgical inſtrument, in uſe among the ancients for elevating the uvula. It is mentioned by Paulus Ægineta.

STAPHYLINUS, in *Anatomy*, the muſcle of the uvula, commonly called azygus. See Deglutition.

Staphylinus, in *Botany*, a name given by ſome authors to the common *daucus ſylveſtris*, wild carrot, or bird's neſt.

Staphylinus, in *Entomology*, a genus of inſects of the order Coleoptera. The generic character is as follows: Antennæ moniliform; four feelers; ſhell half as long as the body; wings folded up under the ſhells; tail not armed with a forceps, furniſhed with two exſertile veſicles. The inſects of this genus are extremely rapacious, devouring not only the inſects of other genera, but frequently each other. Many of them, when attempted to be caught, turn up the tail. The jaws are ſtrong and exſerted, with which they bite and pinch very hard: moſt of them are found in damp moiſt places, among ſubſtances, and a few upon flowers. There are about 180 ſpecies, ſeparated into three ſections, according as their feelers are filiform, hatchet-ſhaped, or clavate. Of theſe we ſhall notice but very few that are not to be found in this country.

Species.

A. *All the Feelers filiform.*

Aureus. Head, thorax, and ſhells, covered with ferruginous down; the abdomen is black, with cinereous bands. It is found in Siam.

* **Hirtus.** Hairy, black; thorax and hind-part of the abdomen yellow. Found in ſandy ſituations, in this country, and other parts of Europe.

* **Murinus.** Pubeſcent, cinereous, clouded; abdomen and legs deep black. It is found in this country, among decayed carcaſes and dung. The ſhells are blue, and poliſhed beneath. The larva is ſix-footed, naked, and of a pale hue. The head and three firſt ſegments of the abdomen cheſnut-brown; tail with two jointed briſtles, and a cylindrical tubercle beneath.

* **Olens.** Black, opaque, immaculate; head broader than the thorax. This is an Engliſh inſect, but found likewiſe in many parts of the European continent.

* **Maxillosus.** Pubeſcent, black, with cinereous bands. The jaws of this inſect are as long as the head; the antennæ are ſtill longer; the ſhell covers one third of the abdomen; the legs end in ſmall tufts of hair.

* **Erythropterus.** Black; ſhells, baſe of the antennæ, and legs, are red; the head and thorax are unpoliſhed, black; ſhells with two triangular ſpots; each ſide is compoſed of a few gilded hairs.

* **Politus.** Black; thorax and ſhells poliſhed; thorax with a line of impreſſed dots. This inſect, when firſt caught, ſcatters a very fragrant odour.

* **Brunnipes.** Black; legs, baſe and tip of the antennæ, ferruginous; the antennæ are black, the firſt and two laſt joints are ferruginous; the eyes are white.

Marginatus. Black; ſides of the thorax and legs are yellow. It is ſomething leſs than the S. politus, and of a gloſſy-black.

Alpinus. Black; baſe of the antennæ, ſhells, and legs, livid. It inhabits the higheſt mountains of Lapland, on the birch. The body of this ſpecies is more depreſſed than is the caſe with regard to others; the antennæ are black, and pale at the baſe; the abdomen is black.

* **Bi-pustulatus.** Black; ſhells with a ferruginous dot behind.

Bi-guttatus. Black; ſhells with a whitiſh dot; the eyes are prominent. It inhabits the ſhores of the Baltic.

* **Fuscipes.** Black; thorax roundiſh; ſhells and legs piceous; the body is ſmall and thick; the edges a little blackiſh.

* **Atricapillus.** Thorax rufous; ſhells brown, with a white dot and hinder margin.

Sanguineus. Gibbous, black; ſhells ſanguineous; antennæ thicker towards the top. This is found chiefly in France. The antennæ are as long as the body; the head is rough; the ſhells are ſtriate at the baſe; legs yellowiſh; thighs brown; body ſometimes cheſnut-brown.

* **Caraboides.** Yellow, immaculate.

* **Rugosus.** Black; thorax and ſhells rugged. It is larger than the next. The head is flat; the thorax depreſſed, with longitudinal wrinkles.

* **Piceus.** Black; thorax depreſſed, with three raiſed lines; the ſhells are piceous.

Flavus. Black; edges of the thorax and ſhells yellow; the latter with a brown fillet and outer margin; antennæ and legs yellow.

Littoreus. Black; ſhells grey on the fore-part; legs rufous. It inhabits the ſea-ſhores.

B. *Hind-feelers hatchet-ſhaped.* Oxyporus.

* **Rufus.** Rufous; head and hind-part of the ſhells and abdomen are black. It is found chiefly on fungi, in this and other European countries.

* **Lunulatus.** Yellow; ſhells black, pale at the baſe and tip. It inhabits Europe, on fungi. Head is black; the tip of the abdomen is marked with a white ring.

* **Merdarius.** Black; thorax and ſhells rufous. It is found in this and other European countries.

* **Chrysomelinus.** Black; thorax rufous; ſhells teſtaceous, the margin at the baſe is black.

* **Rufipes.** Gloſſy-black; legs rufous. It is found in the northern parts of Europe.

* **Hypnorum.** Gloſſy-black; margin of the thorax, ſhells, and legs, teſtaceous; the body is black, glabrous, and poliſhed.

* **Marginellus.** Gloſſy-black; margins of the thorax and ſhells ferruginous. This is a very ſmall inſect.

C. *Fore-feelers clavate.* Pæderus.

* **Riparius.** Rufous; ſhells blue; the head and end of the abdomen are blackiſh. This is figured in Donovan's Engliſh Inſects.

* **Elongatus.** Hind-part of the ſhells and legs fulvous.

Fulgescens. Gloſſy-black; ſhells and ends of the legs teſtaceous; head ſlightly punctured. The head is marked with numerous ſmall impreſſed dots.

STAPHYLIS, a name given by ſome authors to a ſort of cup, or boat, made for feeding young children, and contrived with a ſpout in form of a grape or nipple.

STAPHYLODENDRON. See Staphylæa.

STAPHYLOMA, is the name given, in *Surgery*, to that diſeaſe of the eye, in which the cornea loſes its natural tranſparency, riſes above its proper level, and even projects between the eye-lids, in the form of a whitiſh pearl-coloured tumour, which is attended with total loſs of ſight.

The malady commonly reſults from ſome violent ſpecies of ophthalmy, particularly that which is termed *purulent*, and affects children, and that which is conſequent to the ſmall-pox. As Scarpa obſerves, the ſtaphyloma is one of the moſt ſerious diſeaſes to which the eye-ball is ſubject; for, to the total and irremediable loſs of ſight, are added all the evils which neceſſarily reſult from the protuberance of the cornea in advanced caſes. The inability of cloſing the eye-lids, the expoſure of the eye-ball to the contact of the air and extraneous matter ſuſpended in it, the friction of the eye-laſhes againſt the tumour, the inceſſant flux of tears down the ſubjacent cheek, render the eye painful and inflamed; ſympathetically induce ophthalmy in the ſound one; and cauſe ulceration both on the diſeaſed part of the eye, and on the lower eye-lid and cheek.

The opacity being irremediable, the only ſurgical object is to prevent the inconveniencies ariſing from the protuberance of the diſeaſed cornea. In recent caſes, when the tumour does not project forward, it is beſt to do nothing. In inveterate caſes, the prominent part of the cornea muſt be cut off. Scarpa recommends doing the operation as far from the conjunctiva as the caſe will allow. This eminent ſurgeon introduces a knife, like that uſed in the extraction of the cataract, completely acroſs the ſtaphyloma, at the diſtance of one line and a half, or two lines, from the centre of the tumour.

The lower half of the prominence is to be detached, by puſhing the knife onward, till its edge comes out through the membrane below; then the flap is to be turned up with a pair of forceps, and the inciſion rendered completely circular with the ſame biſtoury. The aqueous humour, cryſtalline lens, and ſome of the vitreous humour, uſually eſcape immediately after the operation, and the eye conſequently becomes ſo diminiſhed as to allow the eye-lids to be ſhut. Ophthalmy and ſuppuration of courſe ſucceed. Emollient poultices are now to be applied, until the violence of the inflammation has abated, the quantity of matter is diminiſhed, and the wound manifeſts a diſpoſition to heal: then they may be left off; and occaſionally touching the ſore with the argentum nitratum, and applying a pledget over the eye, will complete the cicatrization.

Mr. Ware thinks, that the portion of diſeaſed cornea, taken away in the foregoing manner, is too diminutive to allow the cryſtalline lens to eſcape, without bruiſing the iris; and that it ſometimes does not prevent the eye from becoming again diſtended with an aqueous fluid. He has, therefore, adviſed the circular inciſion of the cornea to be made about a quarter of an inch from the junction of that membrane with the ſclerotica. Scarpa ſulle Malattie principali degli Occhi. Ware in Tranſ. of the Med. Society of London, vol. i. art. 6. Cooper's Firſt Lines of Surgery.

STAPHYLOSIS, a protuberance or protruſion of the choroid coat of the eye.

STAPIDACEUS Musculus, in *Anatomy*, a name given by Duverney, Douglas, and many others, to the muſcle of the ſtapes of the ear, called by others *ſtapidis muſculus*, and by Albinus *ſtapidium*. See Stapedius and Ear.

STAPLE, Stapula, primarily ſignifies a public place, or market, whither merchants, &c. are obliged to bring their goods to be bought by the people; as the Greve, or the places along the Seine, for the wines and corns at Paris; whither the merchants of other parts are obliged to bring thoſe commodities.

Voſſius and Menage derive the word from *ſtaplus*, which is found in the Ripuary laws, ſignifying a place where juſtice is adminiſtered. Others derive it from the German *ſtaple*, or Latin *ſtapula*, which Boxhornius derives farther from the German *ſtapelen, to put in a heap*. Others again have obſerved, that the Engliſh word ſtaple is, in the civil law Latin ſtyle of former times, termed *ſtabile emporium*, *i. e.* a fixed port or mart for the importing of merchandize. And hence probably, they ſay, the contracted word *ſtaple* (uſed, with ſome ſmall variation in the orthography, all over Europe) had its derivation.

Staple alſo ſignifies a city or town, where merchants jointly agree to carry certain commodities, as wool, cloth, lead, tin, &c. in order to their being commodiouſly ſold by the great. In England, ſtaples were ſettled and appointed to be conſtantly kept in ſeveral towns, to which places merchants and traders were to carry goods to ſell in thoſe parts. See *Merchants of the* Staple.

The ſtaple commodities of England were chiefly wool, leather, cloth, tin, lead, &c.; though by ſtaple goods are now generally meant any proper ſaleable commodities, not eaſily ſubject to periſh; or ſuch wares and merchandize as are the natural and uſual product or manufacture of any city or country.

The ſtaples in the Levant, called by the French *eſchelles*, *i. e. ſcales*, are ſuch cities where the Engliſh, French, Dutch, Italians, &c. have conſuls, factors, and magazines; and whither they ſend veſſels regularly each year. The principal of theſe are Smyrna, Alexandretta, Aleppo, Seyda, Cyprus, Sallee, Alexandria, Cairo, Tunis, Algiers, Tripoli, the Morea, Candia, and the iſlands of the Archipelago. See Factory.

Staple, *Law of the*. See Law.

Staple, *Merchants of the*, in the *Hiſtory of Engliſh Commerce*, a denomination given to the firſt and moſt ancient commercial ſociety in England, from their exporting the ſtaple wares of the kingdom, which were wool, ſkins, lead, and tin, in their rough ſtate for manufacture. This ſociety is ſaid to have had its riſe in the year 1248; and it appears to have had the legal form of a corporation before the 12th year of Edward II. A.D. 1319; as there are records in the pipe-office of the Exchequer, which mention, that it was actually a corporation, with the title of the mayor and conſtables of the ſtaple of England, who then had their ſtaple at Antwerp, for conducting the ſale of Engliſh ſtaple wares, and the importation of ſuch foreign goods as were wanted at home. However, in 1328, by 2 Edw. III. cap. 9. it was enacted, that the ſtaples, on both ſides of the ſea, ſhould ceaſe, and that all merchant-ſtrangers, &c. might go and come with their merchandize into England, after the tenor of the Great Charter. In 1336 the ſtaple of wool was again fixed in Brabant; in 1341, at Bruges; and in 1348, at Calais; whither, and to no other place, all merchandize exported from England, Wales, and Ireland, either by denizens or aliens, were to be ſhipped from England and there landed. The cuſtoms from this ſtaple are ſaid to have then amounted to upwards of 60,000*l.* ſterling yearly. In 1353, Edward III. removed the ſtaple of wool from Bruges to Weſtminſter, Canterbury, Chicheſter, Exeter, Wincheſter, Briſtol, Lincoln, York, Norwich, Newcaſtle, and Hull, for England; and to Dublin, Cork, Waterford, and Drogheda, for Ireland. And it was enacted by 27 Edward III. called the *ſtatute of the ſtaple*, that all ſtaple wares for exportation ſhould be firſt brought to ſome of theſe places only, where the cuſtom ſhould be paid, and exported by merchant-ſtrangers only, under an oath not to hold any ſtaple thereof beyond ſea; which privilege was extended by 31 Edward III. to denizens alſo. Calais, however, ſtill remained a ſtaple.

In theſe ſtaple-towns, courts of *law-merchant* were eſtabliſhed,

bliſhed, by the ſaid ſtatute, for determining all mercantile affairs, and for puniſhing and amercing offenders. The principal matters under the cognizance of theſe courts were ſuch as pertained to the five ſtaple commodities of England, *viz.* wool and wool-fels or ſheep-ſkins, leather, lead, and tin. From the year 1375, the ſtaple of Weſtminſter ſeems to have been removed to the place called Staple-Inn, in Holborn; when Calais, which had been for many years a principal ſtaple-port for diſperſing, in more early times, the Engliſh wool, lead, and tin, and, in later times, the Engliſh woollen manufactures, under the conduct of the Merchant-Adventurers, into the inland countries of the Netherlands, France, and Germany, was loſt to this country. In 1588, the ſtaple for wool, &c. was eſtabliſhed at Bruges; and queen Elizabeth, in the third year of her reign, granted a new charter of confirmation to the corporation of the mayor and conſtables of the ſtaple of England, of all ſuch privileges as they did, might, or ought to have enjoyed before the loſs of Calais. However, king James I., in 1604, granted a new charter to the Merchant-*Adventurers*, (which ſee,) and in 1617, confirmed all their former powers and privileges for trading to the Netherlands and to Germany, with the woollen manufactures of England, excluſively of all who were not free of their company; in conſequence of which, the merchants of the ſtaple, who had before been declining, by the manufacture and exportation of our woollen cloth, were brought to ruin. And when at length it was judged expedient to enact a total prohibition of the exportation of our wool, it is no wonder that the ſtaplers' company ſhould become extinct. At this day they exiſt only in name; though they maintain the form of a corporation by annually electing the officers of their company, according to the direction of their ancient charters. This nominal corporation is kept up by thoſe who deal in wool (ſtill called wool-ſtaplers), and who, in their corporate capacity, poſſeſs a ſmall ſum in the public funds, the intereſt of which ſerves to defray the expence of their meetings and elections. But they never had a hall, or office of their own, within the city of London, like other trading companies, although the Inn of Chancery in Holborn is ſo denominated from their warehouſes, which were formerly ſituated there; as was alſo an office and warehouſe of theirs, which, ſince the erection of the new bridge at Weſtminſter, has loſt its place, as well as name of wool-ſtaple, at the upper part of Cannon-Row. Anderſon's Hiſt. Com. vol. i. See CUSTOMS.

STAPLE, *Statute.* See STATUTE, and the preceding article.

STAPLE *Articles of Food*, in *Agriculture*, are all thoſe which are of a firm and ſolid nature, texture, and quality, and which afford due ſupport in the feeding and foddering of all ſorts of domeſtic animals of the live-ſtock kind; in contradiſtinction to thoſe which are of a watery and leſs firm ſtructure and conſiſtence, that ſupply nouriſhment and ſupport to ſuch animals in an inferior and leſs perfect manner; as corn, hay, tares, and ſome other ſimilar ſorts of food, in compariſon with thoſe of the more ſucculent root and graſs kinds.

STAPLE *of Land*, a term ſignifying the particular nature and quality of it, in regard to the texture, conſiſtence, and compoſition of its parts as a ſoil. In this way, there are heavy or ſtrong ſtapled lands, thoſe of a medium or middling ſtaple, and light or thin ſtapled lands, according as the particles of the mouldy or powdery materials, of which they are conſtituted, may have more or leſs tenacity, adheſive firmneſs, and ſolidity among themſelves, and more or leſs thickneſs. By this means, the differences in the ſtaples of lands, as ſoils, become of very material importance to the farmer, as they ſhew and teach him not only the nature of the crops that may be grown upon them to the moſt profit and advantage, and with the leaſt danger, or greateſt chance of ſucceſs, but the manner in which they may be the moſt beneficially and effectually cultivated for the raiſing and producing of them. Beſides, the differences in the ſtaples of lands, as ſoils, are the chief or principal means by which the common farmer is able and capable of judging of, and deciding in reſpect to, the qualities of land as farms, as well as of their nature and values in the view of purchaſing them. See SOIL.

STAPLE, *Iron*, in *Rural Economy*, a ſmall piece of iron, in which the outward part is moſtly either of the curved or ſquare form, having two long ſharp ends, points, or prongs, which are driven into wood or any other ſimilar material. Staples of this ſort are very uſeful for many different purpoſes about farms, as faſtening gates, ſecuring doors, and many others of the ſame nature.

STAPLES, or *Keel-Staples*, in *Ship-Building*, are generally made of copper, from ſix to twelve inches long, and about one and a quarter inch broad, with a jagged hook at each end, which are driven into the ſides of the main and falſe keels to faſten them.

STAPLE-*Rope*, a term for ropes made of hemp not inferior to clean Peterſburgh.

STAPLETON, THOMAS, in *Biography*, was born of a good family at Henfield, in Suſſex, in 1535. He was educated partly at Canterbury and partly at Wincheſter, and was then entered of New college, Oxford, of which he became a perpetual fellow. In the reign of queen Mary, he obtained a prebend of Chicheſter, but on the acceſſion of Elizabeth, his ſteady attachment to the Roman Catholic religion cauſed him and his family to remove to Louvain. Here he ſtudied theology, and afterwards viſited Paris and Rome. Returning to Louvain, he employed himſelf in writing books till 1572, when he was invited to Douay, where Philip II. had founded an univerſity. After taking the degree of doctor in theology, he was preſented to a canonry in that town, and was made royal profeſſor of the holy ſcriptures. A diſtaſte to the world induced him to enter among the Jeſuits, who ſent him to Louvain. This ſituation did not at all accord with his taſte, and he returned to the canonry of Douay, whence, in 1590, he was called to occupy a royal profeſſorſhip at Louvain: he was afterwards nominated to the deanery of Hilverbeck, near Bois-le-Duc, a preferment of conſiderable value, the profits of which placed him in good circumſtances. He had now acquired a high reputation by his writings, which procured him an invitation to Rome from pope Clement VIII.; but he felt himſelf too old for ſuch a change, and being beſet with infirmities, he was led to decline the honour intended him. He died in 1598, at the age of ſixty-three. He was a very voluminous writer, and his works, when collected, formed four volumes folio, which were printed at Paris in 1620. They all relate to the principles and controverſies of the Romiſh religion, and the eulogies of its aſſertors. One of the moſt known was entitled "Propugnaculum Fidei primitivæ Anglorum," which was tranſlated into Engliſh under the title of Stapleton's "Fortreſs of Faith." He gave an Engliſh verſion of Bede's Church Hiſtory.

STAPLING *of Wool*, in *Rural Economy*, the art or proceſs of ſorting and adjuſting its different properties and qualities in the ſame fleece, or in the whole quantity, ſo as that thoſe of the ſame kind, and which are proper for the ſame uſe and intention in the manufactures, may be put together in the moſt uſeful and appropriate manner.

The Highland Society of Scotland has lately offered a premium for an eſſay on the beſt mode of executing the buſineſs, and the advantages that may be derived from it to that country. See WOOL.

STAPODIA, or *The Brothers*, in *Geography*, two iſlets in the Grecian Archipelago; 6 miles E. of Mycone. N. lat. 37° 32′. E. long. 36° 42′.

STAPPEN, a place of Iceland, farther along the coaſt towards the W. than Stadarſtad (which ſee); ſituated on the brow of a range of curiouſly columnar rocks, large inſulated maſſes of which ſtand in the ſea, in various ſingular forms. Stappen, like Buderſtad, is a trading ſtation, and conſiſts of a merchant's houſe, two or three ſtore-houſes, and a few cottages, inhabited by fiſhermen. The coaſt in the neighbourhood of Stappen is very remarkable; preſenting, for an extent of about two miles, ſtriking and beautiful columnar appearances, both in the cliffs which form the ſhore, and in the numerous inſulated rocks which appear at different diſtances from the land. The ranges of columns, which in general are about 50 feet high, and perfectly regular in their forms, are variouſly broken, in conſequence of their expoſure to the action of the ſea. In ſome places large caves have been formed; and in two of theſe the light is admitted by fiſſures in the roof, producing a very ſingular and ſtriking effect. In general, the columns have a vertical poſition; but in different places they are diſpoſed in bundles upon one another in all directions. In ſeveral inſtances they appear diverging from a centre; and they aſſume, in ſhort, every form which ſuch rocks can be imagined to take. About a mile and a half W. of Stappen, there is a curious perforated rock, forming a detached arch of conſiderable magnitude, the view through which is ſingularly pictureſque, comprehending in the fore-ground many of the inſulated maſſes of columnar rock, and in the diſtance, the fine range of mountains which ſtretches along the peninſula towards the eaſt. On the beach at Stappen were ſeveral ſharks, that had been taken for the ſake of the oil of the liver, and the ſkin. Of the ſkin ſhoes were made; and ſome parts of the fleſh were occaſionally ſmoked, and uſed as food by the natives. But what they eſteem a delicacy, preſents a moſt horrible odour to ſtrangers. Mackenzie's Travels in Iceland.

STAR, Stella, in *Aſtronomy*, a general name for all the heavenly bodies.

The ſtars are diſtinguiſhed, from the phenomena of their motion, &c. into *fixed* and *erratic*.

Stars, *Erratic*, or *Wandering*, are thoſe whoſe diſtances and places, with regard to each other, are continually changing. Theſe are what we properly call planets. Though to the ſame claſs may likewiſe be referred what we popularly call *blazing* ſtars, or comets.

Stars, *Fixed*, called alſo, by way of eminence, *ſtars*, are thoſe which have been generally obſerved to keep the ſame diſtance with regard to each other, or becauſe (except ſome few) they do not appear to have any proper motion of their own.

The principal points that have come under the conſideration of aſtronomers concerning the fixed ſtars, are, their *diſtance*, *magnitude*, *number*, *nature*, and *motion*.

Stars, *Diſtance of the Fixed*. The fixed ſtars are bodies exceedingly remote from us; indeed ſo remote, that we have no diſtance in the planetary ſyſtem to compare to them.

Their immenſe diſtance is argued hence, that they have no ſenſible parallax, that is, that the diameter of the earth's orbit bears no ſenſible proportion to it; but they are ſeen the very ſame in all the points of it. M. Huygens (Coſmotheor. lib. iv.) attempts to determine the diſtance of the ſtars, by making the aperture of a teleſcope ſo ſmall, as that the ſun through it appears no bigger than Sirius. In this ſtate he found the ſun's diameter to be as 1 to 27,664 of his diameter, when ſeen with the naked eye. Were the ſun's diſtance, then, 27,664 times as great as it is, it would be ſeen of the ſame diameter with Sirius; ſo that, allowing Sirius to be equal in magnitude with the ſun (which is a very reaſonable ſuppoſition), the diſtance of Sirius from the earth will be found to be to that of the ſun from the earth, as 27,664 to 1. On which principle, Sirius will be 657,020,000 ſemidiameters of the earth diſtant from our earth.

Mr. James Gregory inveſtigated the diſtance of Sirius, by ſuppoſing it of the ſame magnitude with the ſun, and of the ſame diameter with Jupiter in oppoſition, as may be ſeen at large in Gregory's Aſtr. lib. iii. prop. 47.

Caſſini (Mem. de l'Acad. ann. 1717), from comparing Jupiter and Sirius, when viewed through the ſame teleſcope, inferred, that the diameter of that planet was ten times as great as that of the ſtar; and the diameter of Jupiter being 50″, he concluded that the diameter of Sirius was about 5″; ſuppoſing then that Sirius is equal to the ſun in magnitude, and the diſtance of the ſun from us to be about 10,000 diameters of the earth, and the apparent diameter of Sirius being to that of the ſun as 1 to 384, the diſtance of Sirius from the earth becomes equal to 3,840,000 diameters of the earth.

Theſe methods of Gregory, Huygens, and Caſſini, are conjectural and precarious, becauſe they ſuppoſe that the ſun and Sirius are equal in magnitude, and principally becauſe they take it for granted, that the diameter of Sirius is determined with ſufficient exactneſs.

Mr. Michell has propoſed an enquiry into the probable parallax and magnitude of the fixed ſtars, from the quantity of light which they afford us, and the particular circumſtances of their ſituation. With this view he ſuppoſes, that they are, at a medium, equal in magnitude and natural brightneſs to the ſun; and then proceeds to enquire what would be the parallax of the ſun, if he were to be removed ſo far from us, as to make the quantity of the light, which we ſhould then receive from him, no more than equal to that of the fixed ſtars. Accordingly, he aſſumes Saturn in oppoſition, excluſively of his ring, (and when the earth and this planet are at their mean diſtances from the ſun,) as equal, or nearly equal, in light to the moſt luminous fixed ſtar. As the mean diſtance of Saturn from the ſun is equal to about 2082 of the ſun's ſemidiameters, the denſity of the ſun's light at Saturn will conſequently be leſs than at his own ſurface, in the proportion of the ſquare of 2082 (or 4,334,724) to 1. If Saturn, therefore, was to reflect all the light that falls upon him, he would be leſs luminous in the ſame proportion; and, beſides, his apparent diameter, in oppoſition, is at moſt but 105th part of that of the ſun, and, conſequently, the quantity of light which we receive from him, muſt be again diminiſhed in the proportion of the ſquare of 105 (or 11,025) to 1. By multiplying theſe two numbers together, we ſhall have the whole of the light of the ſun to that of Saturn, as the ſquare of nearly 220,000 (or 48,400,000,000) to 1: and removing the ſun to 220,000 times its preſent diſtance, he would ſtill appear at leaſt as bright as Saturn, and his whole parallax upon the diameter of the earth's orbit would be leſs than 2″: and this muſt be aſſumed for the parallax of the brighteſt of the fixed ſtars, upon the ſuppoſition that their light does not exceed that of Saturn.

By a ſimilar computation it may be found, that the diſtance at which the ſun would afford us as much light as we receive from Jupiter, is not leſs than 46,000 times his preſent diſtance, and his whole parallax in that caſe, upon the diameter of the earth's orbit, would not be more than 9″; the light of Jupiter and Saturn, as ſeen from the earth, being in the ratio of about 22 to 1, when they are both in oppoſition, and ſuppoſing them to reflect equally in proportion to the whole of the light that falls upon them. But if Jupiter and Saturn, inſtead of reflecting the whole of the light that falls upon them, ſhould really reflect only a part of it, *e. g.* a fourth or a ſixth, which may be the caſe, their diſtances, computed above, muſt be increaſed in the proportion of 2 or $2\frac{1}{2}$ to 1, to make the ſun's light no more than equal to their's; and his parallax would be leſs in the ſame proportion. Suppoſing, then, that the fixed ſtars are of the ſame magnitude and brightneſs with the ſun, it is no wonder that their parallax ſhould hitherto have eſcaped obſervation; ſince, if this is the caſe, it could hardly amount to $2''$, and probably not more than $1''$ in Sirius himſelf, though he had been placed in the pole of the ecliptic; and in thoſe that appear much leſs luminous, *e. g.* γ Draconis, which is only of the third magnitude, it could hardly be expected to be ſenſible with ſuch inſtruments as have hitherto been uſed. However, Mr. Michell ſuggeſts, that it is not impracticable to conſtruct inſtruments, capable of diſtinguiſhing even to the 20th part of a ſecond, provided the air will admit of that degree of exactneſs. This ingenious writer apprehends, that the quantity of light which we receive from Sirius, does not exceed the light which we receive from the leaſt fixed ſtars of the ſixth magnitude, in a greater proportion than that of 1000 to 1, nor in a leſs proportion than that of 400 to 1; and the ſmaller ſtars of the ſecond magnitude ſeem to be about a mean proportional between the other two. Hence, the whole parallax of the leaſt fixed ſtars of the ſixth magnitude, ſuppoſing them of the ſame ſize and native bigneſs with the ſun, ſhould be from about $2'''$ to $3'''$, and their diſtance from about eight to twelve million times that of the ſun: and the parallax of the ſmaller ſtars of the ſecond magnitude, upon the ſame ſuppoſition, ſhould be about $12'''$, and their diſtance about two million times that of the ſun.

This author farther ſuggeſts, that, from the apparent ſituation of the ſtars in the heavens, there is the higheſt probability (the odds againſt the contrary opinion being many million millions to one) that the ſtars are collected together in cluſters in ſome places, where they form a kind of ſyſtem, whilſt in others there are either few or none of them, whether this diſpoſition be owing to their mutual gravitation, or to ſome other law or appointment of the Creator. Hence it may be inferred, that ſuch double ſtars, &c. as appear to conſiſt of two or more ſtars placed very near together, do really conſiſt of ſtars placed near together, and under the influence of ſome general law: and he proceeds to inquire, whether, if the ſtars are collected into ſyſtems, the ſun does not likewiſe make one of ſome ſyſtem, and which are thoſe, among the fixed ſtars, that belong to the ſame ſyſtem with himſelf.

Thoſe ſtars, he apprehends, which are found in cluſters, and ſurrounded by many others at a ſmall diſtance from them, belong probably to other ſyſtems, and not to ours. And thoſe ſtars which are ſurrounded with nebulæ, are probably only very great ſtars, which, on account of their ſuperior magnitude, are ſingly viſible; while the others, which compoſe the remaining part of the ſame ſyſtem, are ſo ſmall as to eſcape our ſight. And thoſe nebulæ in which we can diſcover either none or only a few ſtars, even with the aſſiſtance of the beſt teleſcopes, are probably ſyſtems that are ſtill more diſtant than the reſt.

For other particulars of this inquiry, we muſt refer to Phil. Tranſ. vol. lvii. art. 27. p. 234, &c.

As the diſtance of the fixed ſtars is beſt determined by their parallax, various methods have been purſued, hitherto without ſucceſs, for inveſtigating it; and the reſult of the moſt accurate obſervations has given us little more than a diſtant approximation, from which we may conclude, that the neareſt of the fixed ſtars cannot be leſs than 40,000 diameters of the whole annual orbit of the earth diſtant from us.

The method pointed out by Galileo, and firſt attempted by Hooke, Flamſtead, Molineux, and Bradley, of taking diſtances of ſtars from the zenith that paſs very near it, has given us a much juſter idea of the immenſe diſtance of the ſtars, and furniſhed us with an approximation to the knowledge of their parallax, that is much nearer the truth than we ever had before.

Dr. Bradley aſſures us (Phil. Tranſ. N° 406, or Abr. vol. vi. p. 162.), that, if it had amounted to a ſingle ſecond, or two at moſt, he ſhould have perceived it in the great number of obſervations which he made, eſpecially upon γ Draconis; and that it ſeemed to him very probable, that the annual parallax of this ſtar is not ſo great as a ſingle ſecond, and conſequently, that it is above four hundred thouſand times farther from us than the ſun.

But Dr. Herſchel, to whoſe ingenuity and induſtry in exploring the heavens aſtronomy is already much indebted, and from whom much more may be expected, remarks, that the inſtrument uſed on this occaſion, being the ſame with the preſent zenith ſectors, can hardly be allowed ſufficient to ſhew an angle of one or even two ſeconds with accuracy: and beſides, the ſtar on which the obſervations were made, is only a bright ſtar of the third or ſmall ſtar of the ſecond magnitude; and, therefore, its parallax is probably conſiderably leſs than that of a ſtar of the firſt magnitude: ſo that we are not warranted in inferring that the parallax of the ſtars in general does not exceed $1''$, whereas thoſe of the firſt magnitude may have, notwithſtanding the reſult of Dr. Bradley's obſervations, a parallax of ſeveral ſeconds.

Moreover, the method of zenith diſtances is liable to conſiderable errors, on account of refraction, the change of poſition of the earth's axis ariſing from nutation, preceſſion of the equinoxes, and other cauſes, and the aberration of light.

Dr. Herſchel has propoſed another method, by means of double ſtars, which is free from theſe errors, and of ſuch a nature, that the annual parallax, even if it ſhould not exceed the tenth part of a ſecond, may ſtill become viſible and be aſcertained, at leaſt to a much greater degree of approximation than it ever has been done. This method, which was firſt propoſed in an imperfect manner by Galileo, and has been alſo mentioned by other authors, is capable of every improvement which the teleſcope and mechaniſm of micrometers can furniſh. In order to obtain a general idea of it, let O, E, (*Plate* XX. *Aſtronomy*, *fig.* 8.) be two oppoſite points of the annual orbit, taken in the ſame plane with two ſtars *a*, *b*, of unequal magnitudes. Let the angle *a* O *b* be obſerved when the earth is at O, and *a* E *b* be obſerved when the earth is at E. From the difference of theſe angles, if there ſhould be any, we may calculate the parallax of the ſtars, according to the theory ſubjoined. Theſe two ſtars ought to be as near each other as poſſible, and alſo to differ as much in magnitude as we can find them.

Dr. Herſchel's theory of the annual parallax of double ſtars, with the method of computing from thence what is generally called the parallax of the fixed ſtars, or of ſingle ſtars of the firſt magnitude, ſuch as are neareſt to us, ſuppoſes, *firſt*, that the ſtars, one with another, are about the ſize of the ſun: and, *ſecondly*, that the difference of their apparent magnitudes is owing to their different diſtances, ſo that the ſtar of the ſecond, third, or fourth magnitude, is two, three, or four times as far off as one of the firſt. Theſe principles, which he premiſes as poſtulata, have ſo great a probability in their favour, that they will hardly be objected to by thoſe who are the leaſt acquainted with the doctrine of chances. See Mr. Michell's Inquiry, &c. already cited. Phil. Tranſ. vol. lvii. p. 234. 236, 237. 240. And Dr. Halley on the Number, Order, and Light of the Fixed Stars. Phil. Tranſ. vol. xxxi. or Abr. vol. vi. p. 148.

Accordingly, let O E (*Plate* XX. *Aſtronomy*, *fig.* 9.) be the whole diameter of the earth's annual orbit; and let *a*, *b*, *c*, be three ſtars ſituated in the ecliptic, in ſuch a manner, that they may be ſeen all in one line O *a b c*, when the earth is at O. Let the line O *a b c* be perpendicular to O E, and draw P E parallel to *c* O: then, if O *a*, *a b*, *b c*, are equal to each other, *a* will be a ſtar of the firſt magnitude, *b* of the ſecond, and *c* of the third. Let us now ſuppoſe the angle O *a* E, or parallax of the whole orbit of the earth, to be 1″ of a degree; then we have $PEa = OaE = 1''$: and becauſe very ſmall angles, having the ſame ſubtenſe O E, may be taken to be in the inverſe ratio of the lines O *a*, O *b*, O *c*, &c. we ſhall have $ObE = \frac{1}{2}''$, $OcE = \frac{1}{3}''$, &c. Now when the earth is removed to E, we ſhall have $PEb = EbO = \frac{1}{2}''$, and $PEa - PEb = aEb = \frac{1}{2}''$: *i. e.* the ſtars *a*, *b*, will appear to be $\frac{1}{2}''$ diſtant. We alſo have $PEc = EcO = \frac{1}{3}''$, and $PEa - PEc = aEc = \frac{2}{3}''$; *i. e.* the ſtars *a*, *c*, will appear to be $\frac{2}{3}''$ diſtant, when the earth is at E. Now, ſince we have $bEP = \frac{1}{2}''$, and $cEP = \frac{1}{3}''$, therefore $bEP - cEP = bEc = \frac{1}{2}'' - \frac{1}{3}'' = \frac{1}{6}''$; *i. e.* the ſtars *b*, *c*, will appear to be only $\frac{1}{6}''$ removed from each other, when the earth is at E. Whence we may deduce the following expreſſion, to denote the parallax that will become viſible in the change of diſtance between the two ſtars, by the removal of the earth from one extreme of its orbit to the other. Let P expreſs the total parallax of a fixed ſtar of the firſt magnitude, M the magnitude of the largeſt of the two ſtars, *m* the magnitude of the ſmalleſt, and *p* the partial parallax to be obſerved by the change in the diſtance of a double ſtar; then will $p = \frac{m - M}{Mm} P$; and *p*, being found by obſervation, will give us $P = \frac{pMm}{m - M}$.

E. gr. Suppoſe a ſtar of the firſt magnitude ſhould have a ſmall ſtar of the twelfth magnitude near it: then will the partial parallax we are to expect to ſee be $\frac{12 \times 1\,P}{12 - 1}$, or $\frac{11}{12}$th of the total parallax of a fixed ſtar of the firſt magnitude; and if we ſhould, by obſervation, find the partial parallax between two ſuch ſtars to amount to 1″, we ſhall have the total parallax $P = \frac{1 \times 1 \times 12}{12 - 1} = 1''.0909$. If the ſtars are of the third and twenty-fourth magnitudes, the partial parallax will be $\frac{24 - 3}{3 \times 24} = \frac{21}{72} P$; and if, by obſervation, *p* is found to be a tenth of a ſecond, the whole parallax will come out $\frac{1 \times 3 \times 24}{24 - 3} = 0''.3428$.

Farther, ſuppoſe the ſtars, being ſtill in the ecliptic, to appear in one line, when the earth is in any other part of its orbit between O and E; then will the parallax ſtill be expreſſed by the ſame algebraic formula, and one of the maxima will ſtill lie at O, the other at E: but the whole effect will be divided into two parts, which will be in proportion to each other as radius — ſine to radius + ſine of the ſtars' diſtance from the neareſt conjunction or oppoſition.

When the ſtars are any where out of the ecliptic, ſituated ſo as to appear in one line O *a b c* perpendicular to O E, the maximum of parallax will ſtill be expreſſed by $\frac{m - M}{Mm} P$; but there will ariſe another additional parallax in the conjunction and oppoſition, which will be to that which is found 90° before or after the ſun, as the ſine (S) of the latitude of the ſtars ſeen at O is to the radius (R); and the effect of this parallax will be divided into two parts; half of it lying on one ſide of the large ſtar, the other half on the other ſide of it. This latter parallax, moreover, will be compounded with the former, ſo that the diſtance of the ſtars in the conjunction and oppoſition will then be repreſented by the diagonal of a parallelogram, of which the two ſemi-parallaxes are the ſides; a general expreſſion for which will be $\sqrt{\left(\frac{m - M}{2mM} P\right)^2 \times \frac{SS}{RR} + 1}$; for the ſtars will apparently deſcribe two ellipſes in the heavens, whoſe tranſverſe axes will be to each other in the ratio of M to *m* (*fig.* 10.) and A *a*, B *b*, C *c*, D *d*, will be contemporary ſituations. Now, if *b* Q be drawn parallel to A C, and the parallelogram *b q* B Q be completed, we ſhall have $bQ = \frac{1}{2} CA - \frac{1}{2} ca = \frac{1}{2} Cc = \frac{1}{2} p$, or ſemi-parallax 90° before or after the ſun, and B *b* may be reſolved into, or is compounded of, *b* Q and *b q*; but $bq = \frac{1}{2} BD - \frac{1}{2} bd =$ the ſemi-parallax in the conjunction or oppoſition. We alſo have $R : S :: bQ : bq = \frac{pS}{2R}$; therefore the diſtance B *b* (or D *d*) $= \sqrt{\left(\frac{p}{2}\right)^2 + \left(\frac{pS}{2R}\right)^2}$; and by ſubſtituting the value of *p* into this expreſſion, we obtain $\sqrt{\left(\frac{m - M}{2Mm} P\right)^2 \times \frac{SS}{RR} + 1}$, as above. When the ſtars are in the pole of the ecliptic, *b q* will become equal to *b* Q, and B *b* will be $.7071\, P \frac{m - M}{Mm}$. Again, let the ſtars be at ſome diſtance, *e. g.* 5″, from each other, and let them both be in the ecliptic. This caſe is reſolvable into the firſt; for imagine the ſtar *a* (*fig.* 11.) to ſtand at *x*, and in that ſituation the ſtars *x*, *b*, *c*, will be in one line, and their parallax expreſſed by $\frac{m - M}{Mm} P$. But the angle *a* E *x* may be taken to be equal to *a* O *x*; and as the foregoing formula gives us the angles *x* E *b*, *x* E *c*, we are to add *a* E *x* or 5″ to *x* E *b*, and we ſhall have *a* E *b*. In general, let the diſtance of the ſtars be *d*, and let the obſerved diſtance at E be D; then will $D = d + p$, and therefore the whole parallax of the annual orbit will be expreſſed by $\frac{DMm - dMm}{m - M} = P$.

Suppoſe the two ſtars now to differ only in latitude, one being in the ecliptic, the other, *e. g.* 5″ north, when ſeen at O. This caſe may alſo be reſolved by the former; for imagine the ſtars *b*, *c*, (*fig.* 9.) to be elevated at right angles above the plane of the figure, ſo that *a* O *b*, or *a* O *c*, may make an angle of 5″ at O; then inſtead of the lines O *a b c*, E *a*, E *b*, E *c*, E P, imagine them all to be planes at right angles to the figure; and it will appear, that the parallax of the ſtars in longitude muſt be the ſame as if the ſmall ſtar had been without latitude. And ſince the ſtars *b*, *c*, by the motion of the earth from O to E, will not change their latitude, we ſhall have the following conſtruction for finding the diſtance of the ſtars ab, ac, at E, and from thence the parallax P. Let the triangle $ab\beta$ (*Plate* XX. *Aſtronomy*, *fig.* 12.) repreſent the ſituation of the ſtars; ab is the ſubtenſe of 5″, the angle under which they are to be ſeen at O. The quantity $b\beta$ by the former theorem is found $\frac{m-M}{Mm}P$, which is the partial parallax that would have been ſeen by the earth's moving from O to E, if both ſtars had been in the ecliptic; but on account of the difference in latitude, it will be now repreſented by $a\beta$, the hypothenuſe of the triangle $ab\beta$: therefore in general, putting $ab = d$, and $a\beta = D$, we have $\sqrt{\frac{\overline{DD-dd}\times Mm}{m-M}} = P$. Hence, D being taken by obſervation, and d, M, and m, given, we obtain the total parallax.

If the ſituation of the ſtars differs in longitude as well as latitude, we may reſolve this caſe by the following method. Let the triangle $ab\beta$ (*Plate* XX. *Aſtronomy*, *fig.* 13.) repreſent the ſituation of the ſtars, $ab = d$ being their diſtance ſeen at O, $a\beta = D$ their diſtance ſeen at E. That the change $b\beta$, which is produced by the earth's motion, will be truly expreſſed by $\frac{m-M}{Mm}P$, may be proved as before, by ſuppoſing the ſtar a to have been placed at α. Now let the angle of poſition $ba\alpha$ be taken by a micrometer, or by any other method ſufficiently exact; then, by ſolving the triangle $ab\alpha$, we ſhall have the longitudinal and latitudinal differences $a\alpha$ and $b\alpha$ of the two ſtars. Put $a\alpha = x$, $b\alpha = y$, and it will be $x + b\beta = aq$, whence $D = \sqrt{\left(x + \frac{m-M}{Mm}P\right)^2 + yy}$; and $\sqrt{\frac{\overline{D^2-y^2}\times Mm - xMm}{M-m}} = P$.

If neither of the ſtars ſhould be in the ecliptic, nor have the ſame longitude or latitude, the laſt theorem will ſtill ſerve to calculate the total parallax whoſe maximum will lie in E. There will, moreover, ariſe another parallax, whoſe maximum will be in the conjunction and oppoſition, which will be divided, and lie on different ſides of the large ſtar; but as we know the whole parallax to be exceedingly ſmall, it will not be neceſſary to inveſtigate every particular caſe of this kind; for, by reaſon of the diviſion of the parallax, which renders obſervations taken at any other time, except where it is greateſt, very unfavourable, the formulæ would be of little uſe. Dr. Herſchel cloſes his account of this theory with a general obſervation on the time and place where the maxima of parallax will happen.

When two unequal ſtars are both in the ecliptic, or, not being in the ecliptic, have equal latitudes, north or ſouth, and the largeſt ſtar has moſt longitude, the maximum of the apparent diſtance will be when the ſun's longitude is 90° more than the ſtars, or when obſerved in the morning: and the minimum when the longitude of the ſun is 90° leſs than that of the ſtar, or when obſerved in the evening. When the ſmall ſtar has moſt longitude, the maximum and minimum, as well as the time of obſervation, will be the reverſe of the former. When the ſtars differ in latitude, this makes no alteration in the place of the maximum or minimum, nor in the time of obſervation; *i. e.* it is immaterial whether the largeſt ſtar has the leaſt or the greateſt latitude of the two ſtars. Phil. Tranſ. vol. lxxii. part i. art. 11.

The diſtance of the ſtar γ Draconis appears by Dr. Bradley's obſervations, already recited, to be at leaſt four hundred thouſand times that of the ſun, and the diſtance of the neareſt fixed ſtar not leſs than forty thouſand diameters of the earth's annual orbit: *i. e.* the former is diſtant from the earth at leaſt 38,000,000,000,000 miles, and the latter not leſs than 7,600,000,000,000 miles. As theſe diſtances are immenſely great, it may not be unamuſing to compare them with the velocity of ſome moving body by which they may be meaſured.

The ſwifteſt motion we know of is that of light, (ſee LIGHT,) which paſſes from the ſun to the earth in eight minutes thirteen ſeconds, and yet this would be above ſix years traverſing the firſt ſpace, and nearly 1¼ year in paſſing from the neareſt fixed ſtar to the earth. A cannon-ball diſcharged from a twenty-four pounder, with two-thirds its weight of powder, which moves at the rate of about nineteen miles in a minute (ſee GUN), would be three million eight hundred thouſand years paſſing from γ Draconis to the earth, and ſeven hundred and ſixty thouſand years paſſing from the neareſt fixed ſtar. Sound, which moves at the rate of about thirteen miles in a minute, would be five million ſix hundred thouſand years traverſing the former diſtance, and one million one hundred and twenty thouſand paſſing through the latter.

The celebrated Huygens purſued ſpeculations of this kind ſo far, as to believe it not impoſſible, that there may be ſtars at ſuch inconceivable diſtances, that their light has not yet reached the earth ſince its creation.

Dr. Halley has alſo advanced, what he ſays (Phil. Tranſ. No. 364. or Abr. vol. vi. p. 418.) ſeems to be a metaphyſical paradox, *viz.* that the number of fixed ſtars muſt be more than any finite number, and ſome of them more than at a finite diſtance from others: and Mr. Addiſon has juſtly obſerved, that this thought is far from being extravagant, when we conſider that the univerſe is the work of infinite power, prompted by infinite goodneſs, having an infinite ſpace to exert itſelf in; ſo that our imagination can ſet no bounds to it.

STARS, *The Magnitudes of the Fixed*, appear to be very different, which difference may probably ariſe, not only from a diverſity in their real magnitudes, but principally from their diſtances, which are different.

The ſtars appear of a ſenſible magnitude to the bare eye, becauſe the retina is affected not only by the rays of light which are emitted directly from them, but by many thouſands more, which, falling upon our eye-lids, and upon the aerial particles about us, are reflected into our eyes ſo ſtrongly, as to excite vibrations, not only in thoſe points of the retina where the real images of the ſtars are formed, but alſo in other points at ſome diſtance round about. This makes us imagine the ſtars to be much bigger than they would appear, if we ſaw them only by the few rays which come directly from them, ſo as to enter our eyes without being intermixed with others.

Any one may be ſenſible of this by looking at a ſtar of the firſt magnitude through a long narrow tube, which, though it takes in as much of the ſky as would hold a thouſand ſuch ſtars, ſcarcely renders that one viſible.

The more a teleſcope magnifies, the leſs is the aperture through which the ſtar is ſeen, and conſequently the fewer rays it admits into the eye. Since, therefore, the ſtars appear leſs in a teleſcope which magnifies 200 times, than they do to the bare eye, inſomuch that they ſeem to be only indiviſible points, we may infer that they are at immenſe diſtances from us, and alſo that they ſhine by their own proper light. If they ſhone by borrowed light, they would be as inviſible without teleſcopes as the ſatellites of Jupiter are: for theſe ſatellites appear bigger when viewed with a good teleſcope than the largeſt fixed ſtars do.

The ſtars, on account of their apparently various magnitudes,

nitudes, have been diſtributed into ſeveral claſſes, called *magnitudes*.

The firſt claſs, or ſtars of the firſt magnitude, are thoſe which appear largeſt, and may probably be neareſt us. Next theſe, are thoſe of the ſecond magnitude, and ſo on to the ſixth, which comprehends the ſmalleſt ſtars viſible to the naked eye. All beyond theſe are called *teleſcopic* ſtars. Not that all the ſtars of each claſs appear juſtly of the ſame magnitude; there is great latitude in this reſpect; and thoſe of the firſt magnitude appear almoſt all different in luſtre and ſize. Other ſtars there are, of intermediate magnitudes, which aſtronomers cannot refer to one rather than another claſs, and therefore they place them between the two.

Procyon, for inſtance, which Ptolemy makes of the firſt magnitude, and Tycho of the ſecond, Mr. Flamſtead lays down as between the firſt and ſecond.

Thus, inſtead of ſix ſeveral magnitudes, we may ſay there are almoſt as many orders of ſtars as there are ſtars; ſuch a difference being obſervable in the magnitude, colour, and brightneſs of them.

Whatever room there may be to hope, that we may ſome time or other be able to diſcover the parallax of a few among the fixed ſtars, yet at the ſame time it ſeems probable, that we ſhall never be able to diſcover any ſenſible magnitude in their apparent diameters, which, even in Sirius, if his native brightneſs is not leſs than that of the ſun, muſt be conſiderably leſs, whatever be his parallax, than the hundredth, probably than the two hundredth part of a ſecond; ſo that it could ſcarcely be diſtinguiſhable with a teleſcope, upon the former ſuppoſition, that ſhould magnify ſix, or, upon the latter, with one that ſhould magnify twelve thouſand times. Nor can we well expect to find their apparent diameters from any occultation by the moon, ſince the diameter of a hundredth part of a ſecond would be covered by the moon, if it entered directly, in leſs than the fiftieth part of a ſecond of time, and, therefore, a ſtar can hardly enter ſo obliquely, as to appear to vaniſh by degrees: no ſtar, probably, which the moon can paſs over, ſubtending an angle half ſo great. Nor is it likely there can any thing be determined from occultations by any of the planets. And, therefore, there ſeems to be little chance of diſcovering with certainty the real ſize of any of the fixed ſtars, and we muſt be content to deduce it from their parallax (if that ſhould ever be found) and the quantity of light which they afford us, compared with that of the ſun. Dr. Herſchel, however, informs us, that with a magnifying power of 6450, and by means of his new micrometer, he found the apparent diameter of α Lyræ to be $0''.355$.

The ſtars are likewiſe diſtinguiſhed, with regard to their ſituation, into *aſteriſms*, or *conſtellations*, which are nothing but aſſemblages of ſeveral neighbouring ſtars, conſidered as conſtituting ſome determinate figure, as of an animal, &c. and denominated from it; a diviſion as ancient as the book of Job, in which we find mention of Orion, and the Pleiades, &c. See CONSTELLATION.

Beſides the ſtars thus diſtinguiſhed into magnitudes and conſtellations, there are others not reduced to either. Thoſe not reduced into conſtellations, are called *informes*, (which ſee,) or *unformed ſtars*; of which kind ſeveral, ſo left at large by the ancients, have been ſince formed into new conſtellations by the modern aſtronomers; as *Cor Caroli*, by Dr. Halley; *Scutum Sobieſci*, by Hevelius, &c.

In deſcribing the particular ſtars, it will be moſt convenient to begin with ſuch as never ſet in our climates, and we may then refer the ſituations of others to their poſitions with reſpect to theſe.

The Great Bear is the moſt conſpicuous of the conſtellations which never ſet; it conſiſts of ſeven ſtars, placed like the four wheels of a waggon, and its three horſes, except that the horſes are fixed to one of the wheels. The two hind-wheels are the pointers, which direct us to the pole-ſtar, in the extremity of the tail of the Little Bear: and further on, to the conſtellation Caſſiopeia, which is ſituated in the milky way, where it is neareſt to the pole, and which conſiſts of ſeveral ſtars, nearly in the form of the letter W. The two northernmoſt wheels of the Great Bear, or wain, point at the bright ſtar Capella, the goat, in Auriga. Deſcending along the milky way from Caſſiopeia, if we go towards Capella, we come to Algenib, in Perſeus; and a little further from the pole we find Algol, or Meduſa's head: but if we take the oppoſite direction, we arrive at Cygnus, the ſwan; and beyond it, a little out of the milky way, is the bright ſtar Lyra. The Dragon conſiſts of a chain of ſtars partly ſurrounding the Little Bear; and between Caſſiopeia and the Swan is the conſtellation Cepheus.

Near Algenib, and pointing directly towards it, are two ſtars of Andromeda, and a third is a little beyond them. A line drawn through the Great Bear and Capella paſſes to the Pleiades, and then, turning at a right angle towards the milky way, reaches Aldebaran, or the bull's eye, and the ſhoulders of Orion, who is known by his belt, conſiſting of three ſtars, placed in the middle of a quadrangle. Aldebaran, the Pleiades, and Algol, make the upper, and Menkar, or the whale's jaw, with Aries, the lower points of a W. In Aries we obſerve two principal ſtars, one of them with a ſmaller attendant.

A line drawn from the pole, midway between the Great Bear and Capella, paſſes to the Twins and to Procyon; and then, in order to reach Sirius, it muſt bend acroſs the milky way. Algol and the Twins point at Regulus, the lion's heart, which is ſituated at one end of an arch, with Denebola at the other end.

The pole-ſtar and the middle horſe of the wain direct us to Spica Virginis, conſiderably diſtant: the pole and the firſt horſe nearly to Arcturus, in the waggoner, or Bootes. Much further ſouthwards, and near the milky way, is Antares, in the Scorpion, forming, with Arcturus and Spica, a triangle, within which are the two ſtars of Libra. The Northern crown is nearly in a line between Lyra and Arcturus, and the heads of Hercules and Serpentarius are between Lyra and Scorpio.

In the milky way, below the part neareſt to Lyra, and on a line drawn from Arcturus through the head of Hercules, is Aquila, making with Lyra and Cygnus a conſpicuous triangle. The laſt of the three principal ſtars in Andromeda makes, with three of Pegaſus, a ſquare, of which one of the ſides points to Fomalhaut, ſituated at a conſiderable diſtance in the ſouthern fiſh, and in the neighbourhood of the whale, which has already been mentioned.

By means of theſe allineations, all the principal ſtars that are ever viſible in Britain may be eaſily recogniſed. Of thoſe which never riſe above our horizon, there are ſeveral of the firſt magnitude; Canopus, in the ſhip Argo, and Achernar, in the river Eridanus, are the moſt brilliant of them; the feet of the Centaur, and the Croſier are the next; and, according to Humboldt's obſervations, perhaps ſome others may require to be admitted into the ſame claſs.

Thoſe ſtars not reduced to claſſes or magnitudes, are called *nebulous* ſtars, being ſuch as only appear faintly in cluſters, in form of little lucid nebulæ, or clouds. See NEBULÆ.

Ptolemy ſets down five cloudy ſtars, *viz.* one at the extremity of the right hand of Perſeus, which appears, through the teleſcope, thickly ſet with ſtars; one in the middle of the Crab, called *Præſepe*, or the Manger, in which Galileo counted above forty ſtars; one unformed near the ſting of the Scorpion; the eye of Sagittarius, in which two ſtars may be ſeen in a clear ſky with the naked eye, and ſeveral more with the teleſcope; and one in the head of Orion, in which Galileo counted twenty-one ſtars.

Flamſtead obſerved a cloudy ſtar before the bow of Sagittarius, which conſiſts of a great number of ſmall ſtars, and the ſtar *d* above Sagittarius's right ſhoulder is encompaſſed with ſeveral more.

Caſſini and Flamſtead diſcovered one between the Great and Little Dog, which is very full of ſtars, viſible only by the teleſcope.

But the moſt remarkable of all the cloudy ſtars is that in the middle of Orion's ſword, in which Huygens, and ſince Dr. Long, obſerved twelve ſtars, ſeven of which (three of them, now known to be four, being very cloſe together) ſeem to ſhine through a cloud, very lucid near the middle, but faint and ill-defined about the edges. (See GALAXY, MAGELLANIC *Clouds*, and *Lucid* SPOTS.) Caſſini is of opinion, that the brightneſs of theſe proceeds from ſtars ſo minute, as not to be diſtinguiſhed by the beſt glaſſes: others more probably think, they are large ſpaces in the ether through which a lucid medium is diffuſed. Although moſt of theſe ſpaces are but a few minutes of a degree in breadth, yet, ſince they are among the fixed ſtars, they are probably ſpaces not leſs than our whole ſolar ſyſtem; in which there ſeems to be a perpetual uninterrupted day, which may furniſh matter of ſpeculation, as well to the curious naturaliſt, as to the aſtronomer.

There are alſo ſeveral ſtars which appear ſingle to the naked eye, but are diſcovered by the teleſcope to be double, &c. Of theſe ſeveral have been obſerved by Caſſini, Hooke, Long, Maſkelyne, Hornſby, Pigott, Mayer, &c.; but Dr. Herſchel has been much the moſt ſucceſsful in obſervations of this kind. Beſides the ſkill and induſtry by which he is no leſs diſtinguiſhed than other aſtronomers who have been employed in celeſtial obſervations, his ſucceſs has been chiefly owing to the very extraordinary magnifying powers of the Newtonian ſeven-feet reflector which he has uſed, and the advantage of an excellent micrometer of his own conſtruction. The powers which he has uſed have been 146, 227, 278, 460, 754, 932, 1159, 1536, 2010, 3168, and even 6450. His obſervations appear to commence with the year 1776, but almoſt all of them were made in the years 1779, 1780, 1781; and they have been ſince continued with the ſame ſkill and general aſſiduity. For the reſult, we refer to the articles DOUBLE *Stars*, GALAXY, HEAVENS, NEBULA, NEBULOSITY, and the ſequel of this article.

STAR, *Double*, or a *Binary Sidereal Syſtem*, is formed by two ſtars ſituated ſo near to each other, as to be kept together by their mutual gravitation. The two bodies may revolve round their common centre of gravity in circles, or in ſimilar ellipſes, the dimenſions of their orbits being proportional to their relative quantities of matter. From a ſeries of obſervations on double ſtars, Dr. Herſchel has found that they have changed their ſituations with regard to each other, that the one performs a revolution round the other, and that the motion of ſome of them is direct, while that of others is retrograde. In the courſe of obſervations purſued for twenty-five years, he diſcovered that in more than fifty of the double ſtars, there is a change either in the diſtance of the two ſtars, or in the angle made by a line joining them with the direction of their daily motion, which he calls "the angle of poſition." The intereſting obſervations that have been publiſhed (Phil. Tranſ. vol. lxxiii.) relate to ſix double ſtars, α Geminorum, γ Leonis, ε Bootes, ζ Herculis, δ Serpentis, and γ Virginis. In reſpect to the firſt of theſe, Caſtor or α Geminorum, the angle of poſition was found to have diminiſhed in the ſpace of 43 years 142 days, 45° 39′; and from the regularity of its decreaſe, he thinks it highly probable that the orbits in which the two ſtars move round their common centre of gravity are nearly circular, and at right angles to the line in which we ſee them; and that the time of a whole apparent revolution of the ſmall ſtar round Caſtor will be nearly 342 years and 2 months, in a retrograde direction. From the year 1778 to 1803, he never could perceive any variation in the diſtance of the two ſtars, which was uniformly $1\frac{7}{8}$ of the diameter of the large one. The diſtance of the two ſtars which compoſe γ Leonis has undergone a decided change from February 16th, 1782, to March 26th, 1803. The diameters of the two ſtars were as 5 to 4. The angle of poſition had diminiſhed in this time from 7° 37′ N. following, to 6° 21′ S. following. From the interval between the two ſtars, the ratio of their diameters, and the variation in the angle of poſition, Dr. Herſchel has found that the apparent orbit of the ſmall ſtar is elliptical, and that it performs a whole revolution in about 1200 years, in a retrograde direction. The beautiful double ſtar of ε Bootes is compoſed of two ſtars, one of which is of a light red, and the other of a fine blue, having the appearance of a planet and its ſatellite. The diſtance between the two ſtars, obſerved with a power of 460, and an aperture of 6.3 inches, in 1781, was $1\frac{1}{2}$ the diameter of the large ſtar, and in 1803, the interval had increaſed to $1\frac{3}{4}$ of that diameter. The ratio of the ſize of the ſtars is as 3 to 2. The angle of poſition appeared to have ſuffered a change of 12° 33′, in the ſpace of 22 years and 207 days. From theſe facts Dr. Herſchel concludes that the orbit of the ſmall ſtar is elliptical, and performs its revolution, according to the order of the ſigns, in 1681 years. The double ſtar ζ Hercules is compoſed of a greater and a leſſer ſtar; the former being of a beautiful blueiſh-white, and the latter of a fine aſh-colour. On the 18th July, 1782, the interval between the two ſtars was one half the diameter of the ſmaller one, with a power of 460. On the 21ſt July of the ſame year, their diſtance remained the ſame, but with a power of 987; they were one full diameter of the ſmall ſtar aſunder. In 1795, Dr. Herſchel found it difficult to perceive the ſmall ſtar. In the month of October 1795, however, he ſaw it diſtinctly with a power of 460. In 1802, he could no longer perceive the ſmall ſtar, but in a clear night in September of that year, with a power of 460, the apparent diſc of ζ Hercules ſeemed to be a little lengthened in one direction. With the ten-feet teleſcope, and a power of 600, it had the appearance of a lengthened, or rather wedge-formed, ſtar. With a power of 2140, he again examined it on the 11th of April, 1803, and found the diſc a little diſtorted; but he was convinced that not more than three-eighths of the apparent diameter of the ſmall ſtar was wanting to a complete occultation. The angle of poſition, on the 21ſt July, 1782, was 20° 42′ north following.

The double ſtar of δ Serpentis has, like ε Bootes, undergone a conſiderable change in the angle of poſition, without any variation in the diſtance between the two ſtars. On the 5th September, 1782, the angle of poſition was 42° 48′ ſouth preceding; and on the 7th February 1802, it was 61° 27′ ſouth preceding, having ſuſtained a diminution of 18° 39′ in the ſpace of 19 years and 155 days. Hence the period of a complete revolution of the ſmaller ſtar will be about 375 years.

The double ſtar of γ Virginis, which has long been known to aſtronomers, is compoſed of two ſtars, which Dr. Herſchel at firſt conſidered as nearly equal, though he has ſince aſcertained that the one is a little larger than the other. Their diſtance, which is about 2½ diameters, has continued the ſame for 21 years, while the angle of poſition has varied conſiderably. On the 21ſt November, 1781, the angle of poſition was 40° 44′ ſouth following, or rather north preceding, ſince the other ſtar was afterwards found to be the ſmaller of the two; and on the 15th April, 1803, the angle of poſition was 30° 20′ north preceding, having ſuffered a diminution of 10° 24′ in 21 years and 145 days. From an obſervation of Mayer's, however, in 1756, Dr. Herſchel has found the angle of poſition for that year to be 54° 21′ 37″ north preceding, which gives a motion of 24° 2′ in 47 years and 105 days. Hence he concludes, that a complete revolution is performed in about 708 years.

For a catalogue, ſuch as our limits would allow, of the principal double ſtars, ſee the article DOUBLE *Stars*.

For an account of cluſtering ſtars, cluſters of ſtars, and groups of ſtars, and alſo treble, quadruple, quintuple, and multiple ſyſtems of ſtars, we muſt refer to the articles GALAXY and HEAVENS; and for a more particular detail, and catalogues of them, to Dr. Herſchel's papers, or to the 2d volume of Ferguſon's Aſtronomy, by Dr. Brewſter.

STARS, *Inſulated*, a name applied by Dr. Herſchel to thoſe celeſtial bodies which are in a great degree out of the reach of the attractive force of other ſtars, ſuch as our Sun, Arcturus, Capella, Lyra, Sirius, Canobus, Markab Bellatrix, Menkar, Shedir, Algorah, Propus, and probably many others. It is obvious that no two ſtars in the univerſe can be altogether out of the ſphere of each other's attraction; but in the caſe of Sirius and our ſun, which, upon the ſuppoſition that their maſſes are equal, and that the former has a parallax of 1″, would take 33 millions of years to fall to one another by their mutual action, we are entitled to ſay that they are inſulated. Inſulated ſtars are conſidered by Dr. Herſchel as the centres of extenſive planetary ſyſtems like our own; an opinion which he deduces from analogy, and from the nature of other ſidereal combinations. Inſtead of ſuppoſing, therefore, as has generally been done, that every ſtar in the firmament is encircled with planets, ſatellites, and comets, Dr. Herſchel believes that the inſulated ſtars alone are ſurrounded with ſuch numerous attendants.

STARS, called *Nebulæ.* (See NEBULÆ, NEBULOSITY, and the articles to which we have above referred.) Mr. Michell has ſhewn, from the computation of probabilities, that it is many million million chances to one, that the ſtars, which appear to form double ſtars, &c. cluſters and nebulæ in the heavens, are really collected together into ſeparate ſyſtems. In the caſe of the Pleiades, for example, he computes that it is 500,000 to 1, that no ſix ſtars out of the number of thoſe that are equal to the fainteſt of them in ſplendour, ſcattered at random in the whole heavens, ſhould be within ſo ſmall a diſtance from each other as the Pleiades are.

A ſimilar opinion was maintained by profeſſor Kant and M. Lambert, who ſuppoſed that all the ſtars in the univerſe are collected into nebulæ; and that all the inſulated or ſcattered ſtars which appear in the heavens, belong to the particular nebula in which our ſyſtem is placed. We are indebted, however, ſolely to the genius and induſtry of Dr. Herſchel, for perfecting theſe ſagacious views, and ſupporting them by a body of evidence amounting nearly to demonſtration. He has obſerved the poſition, magnitude, and ſtructure of no fewer than 2500 nebulæ. He generally detected them in certain directions, rather than in others; and in many parts of the heavens there were vacant ſpaces, both preceding and following the nebulous ſtrata. Dr. Herſchel ſuppoſes the nebula in Cancer, and that of Coma Berenices, to belong to two ſtrata which are neareſt the nebula of the Milky Way.

The following catalogue of nebulæ, copied from Dr. Brewſter's edition of Ferguſon's Aſtronomy, is founded chiefly on the obſervations of Meſſier, as given in the "Connoiſſance des Tems" for 1784, the more recent obſervations of Dr. Herſchel being always added. The *firſt* column contains the number of the nebulæ, and the time when the obſervation was made; the *ſecond* and *third*, its right aſcenſion and declination for that time, which are more convenient than their longitude and latitude for finding them on a celeſtial globe. The *fourth*, its diameter in degrees and minutes; and the laſt, ſome general remarks on its appearance. All the nebulæ in this claſs may be ſeen with good teleſcopes of a moderate ſize.

Catalogue of 103 Nebulæ, the Poſitions of which have been determined by Meſſier.

No. and Year when obſerved	Poſition of the Nebulæ.	Right Aſcen. in Degrees.	Declination.	Diamet.	General Remarks.
1. 1758.	Above the Bull's ſouthern horn, weſt of ζ -	80 0 33	21 45 27 N.		A whitiſh light, elongated like the flame of a taper. It exhibited a mottled nebuloſity to Dr. Herſchel.
2. 1760.	In the head of Aquarius, near the 24th ſtar -	320 17 0	1 47 0 S.	4′	It is like the nucleus of a comet, ſurrounded with a large round nebula. Dr. H. reſolved it into ſtars.
3. 1764.	Between Arcturus and Cor Caroli - -	202 51 19	29 32 57 N.	3′	It is round, bright in the centre, and fades away gradually. It exhibited a mottled nebuloſity to Dr. H.
4.	Near Antares - -	242 16 56	25 55 40 S.	2½′	A maſs of ſmall ſtars.
5.	Near 6 Serpent - -	226 39 4	2 57 16 N.	3′	A round nebula. Reſolved into ſtars by Dr. H.
6.	Between the bow of Sagittarius and the tail of Scorpio - - -	261 10 39	32 10 34 S.	15′	A maſs of ſmall ſtars.
7.	Near the preceding - -	264 30 24	34 40 34 S.	30′	A maſs of ſmall ſtars.
8.	Between the bow of Sagittarius, and the right foot of Ophiuchus -	267 29 30	24 21 10 S.	30′	An elongated maſs of ſtars. Near this maſs is the 9th of Sagittarius, which is encircled with a faint light.

No. and Year when obſerved.	Poſition of the Nebulæ.	Right Aſcen. in Degrees.	Declination.	Diamet.	General Remarks.
9.	In the right leg of Ophiuchus - - -	256 20 36	18 13 26 S.	3′	Round and faint; but reſolved by Dr. Herſchel into ſtars.
10.	In the girdle near 30 Ophiuchus - -	251 12 6	3 42 18 S.	4′	A fine and round nebula. Reſolved into ſtars by Dr. H.
11.	Near K. Antinous - -	279 35 43	6 31 1 S.	4′	A maſs of many ſmall ſtars, mixed with a faint light.
12.	Between the arm and the left ſide of Ophiuchus	248 43 10	2 30 28 S.	3′	Round and faint. Near it is a ſtar of the 9th magn. Reſolved by Dr. H. into ſtars.
13.	In the girdle of Hercules, between two ſtars of the 8th magnitude - -	248 18 48	36 54 44 N.	6′	Round and bright in the middle. Reſolved by Dr. H. into ſtars.
14.	In the drapery over the R. arm of Ophiuchus	261 18 29	3 5 45 S.	7′	Round and faint. Near a ſtar of the 9th magn. Reſolved into ſtars by Dr. H.
15.	Between the head of Pegaſus, and that of the Little Horſe - -	319 40 19	10 40 3 N.	3′	Round and bright in the centre. Reſolved into ſtars by Dr. H.
16.	Near the Serpent's tail -	271 15 3	13 51 44 N.	8′	A maſs of ſmall ſtars, mixed with a faint light, reſolved by Dr. H.
17.	North of the bow of Sagittarius - - -	271 45 48	16 14 44 S.	5′	A train of faint light, with ſtars.
18.	Above the preceding -	271 34 3	17 13 14 S.	5′	A maſs of ſmall ſtars ſurrounded with nebuloſity.
19.	Between Scorpio and the R. foot of Ophiuchus	252 1 45	25 54 46 S.	3′	Round, and reſolved into ſtars by Dr. H.
20.	Between the bow of Sagittarius and the right foot of Ophiuchus -	267 4 5	22 59 10 S.		A maſs of ſtars of the 8th and 9th magnitude, ſurrounded with nebuloſity.
21.	Near 11 Sagittarius - -	267 31 35	22 31 25 S.		The ſame as the preceding.
22.	Near 25 Sagittarius - -	275 28 39	24 6 11 S.	6′	Round, and reſolved into ſtars by Dr. H.
23.	Near 65 Ophiuchus - -	265 42 50	18 45 55 S.	15′	A maſs of ſtars very near each other.
24.	Near the end of the bow of Sagittarius in the Milky Way - -	270 26 0	18 26 0 S.	1° 30′	Great nebuloſity, containing ſeveral ſtars. The light is divided into ſeveral parts. Reſolved into ſtars by Dr. H.
25.	Near the preceding, near 21 Sagittarius - -	274 25 0	19 5 0 S.	10′	A maſs of ſmall ſtars.
26.	Near *n* and *o* Antinous -	278 5 25	9 38 14 S.	2′	A maſs of ſmall ſtars.
27.	Near 14 of the Fox - -	297 21 41	22 4 0 N.	4′	Oval. It exhibited a mottled nebuloſity to Dr. H.
28.	A degree from λ Sagittarius - - -	272 29 30	24 57 11 S.	2′	Round, and reſolved into ſtars by Dr. H.
29.	Below γ Cygni - -	303 54 29	37 11 57 N.		A maſs of 7 or 8 ſmall ſtars.
30.	Near 41 Capricorn - -	321 46 18	24 19 4 S.	2′	Round, and reſolved into ſtars by Dr. H.
31.	In Andromeda's girdle -	7 26 32	39 9 32 N.	40′	It reſembles two cones of light joined at their baſe, which is 15′ broad. Reſolved into ſtars by Dr. H.
32.	Below the preceding -	7 27 32	38 45 34 N.	2′	Round, without ſtars, and with a faint light.
33.	Below the head of the N. Fiſh and the Great Triangle - - -	20 9 17	29 32 23 N.	15′	Its light is uniform and whitiſh. It exhibited a mottled nebuloſity to Dr. H.
34.	Between Meduſa's head and the left foot of Andromeda - -	36 51 37	41 39 32 N.	15′	A maſs of ſmall ſtars.
35.	Near μ and η Caſtor -	88 40 9	24 33 30 N.	20′	A maſs of ſmall ſtars near Caſtor's left foot.
36.	Near φ Bootes - -	80 11 42	34 8 6 N.	9′	A maſs of ſmall ſtars.
37.	Near the preceding - -	84 15 12	32 11 51 N.	9′	A maſs of ſmall ſtars with a nebuloſity, reſolved into ſtars by Dr. H.
38.	Near σ Auriga - -	78 10 12	36 11 51 N.	15′	A ſquare maſs of ſmall ſtars.
39.	Near the Swan's tail -	320 57 10	47 25 0 N.	1° 0′	A maſs of ſmall ſtars.
40.	At the root of the Great Bear's tail - -	182 45 30	59 23 50 N.		Two ſtars very near one another
41.	Below Sirius - -	98 58 12	20 33 0 S.		A maſs of ſmall ſtars.

STARS.

No. and Year when obſerved.	Poſition of the Nebulæ.	Right Aſcen. in Degrees.	Declination.	Diamet.	General Remarks.
1765. 42.	Between θ and *c* in Orion's ſword	80 59 40	5 34 6 S.	6′	A beautiful nebula, containing ſeven ſmall ſtars.
1769. 43.	Above the preceding	81 3 0	5 26 37 S.		A ſtar ſurrounded with nebuloſity.
44.	Between γ and δ Cancer	126 50 30	20 31 38 N.		A maſs of ſmall ſtars.
45.	The Pleiades	53 27 4	23 22 41 N.		Cluſter of ſtars.
46. 1771.	Between the G. Dog's head and the hind feet of the Unicorn	112 47 43	14 19 7 S.		A maſs of ſtars, with a little nebuloſity.
47.	Near the preceding	116 3 58	14 50 8 S.		A maſs of ſmall ſtars.
48.	Near the three ſtars at the root of the Unicorn's tail	120 36 0	1 16 42 S.		A maſs of ſmall ſtars.
49.	Near ρ Virgo	184 26 58	9 16 9 N.		See Mem. Acad. 1779.
50. 1772.	Above θ Great Dog	102 57 28	7 57 42 S.		A maſs of ſmall ſtars below the Unicorn's right thigh.
51. 1774.	Below η Great Bear. Near the ear of the Northern Greyhound	200 5 48	48 24 24 N.		Double. The two atmoſpheres, whoſe centres are 4′ 35″ diſtant, touch one another, and are bright in the middle. The one is fainter than the other. Reſolved into ſtars by Dr. Herſchel.
52.	Below *d* Caſſiopeiæ	348 39 27	60 22 12 N.		Maſs of ſtars, mixed with a nebuloſity, according to Dr. H. This cluſter appears like a ſolid ball, conſiſting of ſmall ſtars, quite compreſſed into one blaze of light, with a great number of looſe ones ſurrounding it.
53.	Near 42 Berenice's hair	195 30 26	19 22 44 N.		Round, and reſolved into ſtars by Dr. H.
1777. 54.	In Sagittarius	280 12 55	30 44 1 S.	6′	Faint and bright in the centre.
1778. 55.	In Sagittarius	291 30 25	31 26 27 S.		A white ſpot, reſolved into ſtars by Dr. H.
56.	Near the Milky Way	287 0 1	29 48 14 N.		Faint, and reſolved into ſtars by Dr. H.
1779. 57.	Between γ and β Lyra	281 20 8	32 46 3 N.		Round, and conſiſting of a mottled nebuloſity.
58.	In Virgo	186 37 23	13 2 42 N.		Very faint, without any ſtar.
59.	Near the preceding	187 41 38	12 52 36 N.		Very faint, without any ſtar.
60.	In Virgo	188 6 53	12 46 2 N.		Brighter than the two preceding.
61.	In Virgo	182 41 5	5 42 5 N.		Very faint.
62.	In Scorpio	251 48 24	29 45 30 S.		Like a comet, with a brilliant centre, ſurrounded with a faint light. Reſolved into ſtars by Dr. H.
63.	In the Canes Venatici	196 5 30	43 12 37 N.		Very faint.
64.	In Berenice's hair	191 27 38	22 52 31 N.		Faint.
1780. 65.	In the Lion	166 50 54	14 16 8 N.		Faint, but reſolved into ſtars by Dr. H.
66.	Very near the preceding	167 11 39	14 12 21 N.		Very faint, but reſolved into ſtars by Dr. H.
67.	Below the ſouthern claw of the Crab	129 6 57	12 36 38 N.		A maſs of ſtars, with nebuloſity. It is a cluſter, pretty much compreſſed, in which Dr. H. has obſerved 200 ſtars at once, with a power of 157 in his great reflector.
68.	Below the Crow	186 54 33	25 30 20 S.	2′	Very faint.
69.	Below the left arm of Sagittarius	274 11 46	32 31 45 S.	2′	Faint, like the nucleus of a ſmall comet.
70.	Near the preceding	277 13 16	32 31 7 S.	2′	Near four teleſcopic ſtars.
71.	Between γ and δ Arrow	295 59 9	18 13 0 N.	3′ 30″	Very faint, and reſolved into ſtars by Dr. H.
72.	Above the tail of Capricorn	310 20 49	13 20 51 S.	2′	Faint, but reſolved into ſtars by Dr. H.
73.	Near the preceding	311 43 4	13 28 40 S.		Three or four ſmall ſtars, containing a little nebuloſity.

No. and Year when obſerved.	Poſition of the Nebulæ.	Right Aſcen. in Degrees.	Declination.	Diamet.	General Remarks.
74.	Near η in the ſtring that connects the Fiſhes -	21 14 9	14 39 35 N.		Very faint, but reſolved into ſtars by Dr. Herſchel.
75.	Between Sagittarius and the head of Capricorn	298 17 24	22 32 23 S.		Compoſed of ſmall ſtars, with nebuloſity. Mechain makes it only nebulous.
76.	In Andromeda's right foot	22 10 47	50 28 48 N.	2′	Compoſed of ſmall ſtars, with nebuloſity. Small and faint.
77.	In the Whale - - -	37 52 33	0 57 43 S.		A maſs of ſmall ſtars, containing nebuloſity.
78.	In Orion - - -	83 53 35	0 1 23 S.	3′	A maſs of ſtars, with two bright nuclei, ſurrounded with a nebuloſity.
79.	Below the Hare - -	78 49 2	24 42 57 S.		A fine nebula, bright in the centre, and a little diffuſed. Reſolved into a mottled nebuloſity by Dr. H.
80.	Between g and δ Scorpio -	240 59 48	22 25 13 S.	2′	Round and bright in the centre, like a comet.
1781. 81.	Near the ear of the Great Bear - - -	144 27 44	70 7 24 N.		A little oval, bright in the centre, and exhibiting a mottled nebuloſity to Dr. H.
82.	Near the preceding - -	144 29 22	70 44 27 N.		Faint, and elongated, with a teleſcopic ſtar at its extremity. It ſhewed a mottled nebuloſity to Dr. H.
83.	Near the Centaur's head -	201 8 13	28 42 27 S.		Very faint.
84.	In Virgo - - -	183 30 21	14 7 1 N.		Bright in the centre, and ſurrounded with nebuloſity.
85.	Above and near Spica -	183 35 21	19 24 26 N.		Very faint.
86.	In Virgo - - -	183 46 21	14 9 52 N.		The ſame as N° 84, and near it.
87.	In Virgo - - -	184 57 6	13 38 1 N.		As luminous as the preceding.
88.	In Virgo - - -	185 15 49	15 37 51 N.		Very faint, and like N° 58.
89.	Near N° 87 - - -	186 9 36	13 46 49 N.		Very faint.
90.	In Virgo - - -	186 27 0	14 22 50 N.		Like the preceding.
91.	Above the preceding -	186 37 0	14 57 6 N.		Fainter than the preceding.
92.	Between the knee and the left leg of Hercules -	257 38 3	43 21 59 N.	5′	A beautiful nebula, bright in the centre, and ſurrounded with great nebuloſity. Reſolved into ſtars by Dr. H.
93.	Between the Great Dog and the Ship - -	113 48 35	23 19 45 S.	8′	A maſs of ſmall ſtars.
94.	Above Cor Caroli - -	190 10 46	42 18 43 N.	2′ 30″	Bright in the centre, with a diffuſed nebuloſity.
95.	In the Lion, above *l* - -	158 3 5	12 50 21 N.		Very faint.
96.	Near the preceding - -	158 46 20	12 58 9 N.		Fainter than the preceding.
97.	Near β Great Bear - -	165 13 40	56 13 30 S.	2′	Very faint. Another near it, and another near γ.
98.	Above N. wing of Virgo -	180 50 49	16 8 15 N.		Very faint.
99.	On the N. wing of Virgo -	181 55 19	15 37 12 N.		Brighter than the preceding. Between two ſtars of the 7th and 8th magnitude.
100.	In the ear of corn in Virgo	182 59 19	16 59 21 N.		Like the preceding.
101.	Between the left hand of Bootes and the tail of the Great Bear - -	208 52 4	55 24 25 N.	7′	Very faint. Diſcovered by Mechain. Mottled nebuloſity, according to Dr. H.
102.	Between ο Bootes and ι Dragon - - -	- - -	- - -		Very faint. Diſcovered by Mechain.
103.	Between ε and δ Caſſiopeiæ	- - -	- - -		A maſs of ſtars.

Star, *Nebulous*, is a luminous point, ſurrounded with an immenſe viſible atmoſphere. Dr. Herſchel thinks, that the central point is a ſtar, from its complete reſemblance to a ſtar of equal magnitude. Allied to theſe are planetary nebulæ, or circular ſpaces in the heavens, uniformly luminous, reſembling a planetary diſc. The light of one of theſe nebulæ, 15″ in diameter, was hardly equal to that of a ſtar of the 8th or 9th magnitude. Hence Dr. Herſchel ſuppoſes, that they can ſcarcely be bodies like our ſun, as a part of the ſun's diſc, 15″ in diameter, would exceed the greateſt luſtre of the full moon. If, on the other hand, he obſerves, we ſhould ſuppoſe them to be groups or cluſters of ſtars, at a diſtance ſufficiently great to reduce them to ſo ſmall an apparent diameter, we ſhall be at a loſs to account for their uniform light, if cluſters; or for their circular forms, if mere groups of ſtars. Perhaps they may be rather allied to nebulous ſtars; for, ſhould the planetary nebulæ, with lucid centres, be an intermediate ſtep between planetary nebulæ and nebulous ſtars, the appearances of theſe different ſpecies, when all the individuals of them are fully examined, might throw a conſiderable light on the ſubject. The claſs of planetary nebulæ with centres differs only from the laſt in having a bright central point. See Nebulosity.

Catalogue of Two Hundred and Eighty-eight of the Claſs of Bright Nebulæ, according to the Obſervations of Dr. Herſchel:—F. ſignifying following, P. preceding, N. north, and S. ſouth.

Number.	Stars by which the Nebulæ may be found.	Differ. of Right Aſcenſion in Time between the Nebulæ and the Star.			Difference in Declination.

A table of nebulæ in the ſouthern hemiſphere, by La Caille, may be ſeen in the "Connoiſſance des Tems" for 1784, p. 270.

Stars, *The Number of*, appears to be vaſtly great, almoſt infinite; yet have aſtronomers long ago aſcertained the number of thoſe viſible to the eye, which are found much fewer than one might imagine. See Catalogue *of the Stars*.

Of the 3000 contained in the Britannic Catalogue, there are many only viſible through a teleſcope; nor does a good eye ſcarcely ever ſee more than a thouſand at the ſame time in the cleareſt heaven; the appearance of innumerable more, frequent in clear winter nights, ariſing from our ſight's being deceived by their twinkling, and from our viewing them confuſedly, and not reducing them to any order. Yet, for all this, the ſtars are really almoſt infinite. See Halley on the Number, Order, and Light of the fixed Stars, Phil. Tranſ. N° 364, or Abr. vol. vi. p. 148.

Riccioli makes no ſcruple to affirm, in his New Almageſt, that a man who ſhould ſay there are above twenty thouſand times twenty thouſand, would ſay nothing improbable.

For a good teleſcope, directed to almoſt any point of the heavens, diſcovers numbers that are loſt to the naked ſight; particularly in the Milky Way, which Dr. Herſchel has aſcertained to be an aſſemblage of ſtars, too remote to be ſingly ſeen, but ſo cloſely diſpoſed as to give a luminous appearance to that part of the heavens where they are. See Galaxy.

In the ſingle conſtellation of the Pleiades, inſtead of 6, 7, or 8 ſtars ſeen by the beſt eye, Dr. Hooke, with a teleſcope 12 feet long, told 78, and with larger glaſſes many more of different magnitudes. And F. de Rheita, a Capuchin, affirms, that he has obſerved above 2000 ſtars in the ſingle conſtellation of Orion.

The ſame author found above 188 in the Pleiades. And Huygens, looking at the ſtar in the middle of Orion's ſword, inſtead of one found it to be twelve. Galileo found 80 in the ſpace of the belt of Orion's ſword, 21 in the nebulous ſtar of his head, and above 500 in another part of him, within the compaſs of one or two degrees ſpace, and more than 40 in the nebulous ſtar Præſepe. See *Magnitudes of the* Stars, *ſupra*.

If an ordinary teleſcope, therefore, will, in ſeveral parts of the heavens, diſcover ten times as many ſtars as are viſible to the naked eye, what may not be expected from the improved magnifying powers of modern times?

Stars, *The Changes that have happened in the*, are very conſiderable; contrary to the opinion of the ancients, who held, that the heavens and heavenly bodies were incapable of any change, the matter of which being permanent and eternal, infinitely exceeding the hardneſs of diamonds, and not ſuſceptible of any different form. And, in effect, till the time of Ariſtotle, and even two hundred years afterwards, there had no change been obſerved. The firſt was above 120 years before the incarnation; when Hipparchus, diſcovering a new ſtar to appear, was firſt induced to make a catalogue of the ſtars, that poſterity might perceive any future changes of the like kind. (See Catalogue.) The number of ſtars which are aſcertained to be variable, amounts only to 15; while thoſe which are ſuſpected to be variable, amount to 37.

In the year 1572, Cornelius Gemma and Tycho Brahe obſerved another new ſtar in the conſtellation Caſſiopeia, which was, likewiſe, the occaſion of Tycho's making a new catalogue. Its magnitude and brightneſs, at firſt, exceeded that of the biggeſt of our ſtars, Sirius and Lyra; it even equalled that of Venus when neareſt the earth, and was ſeen in fair day-light. It continued ſixteen months; towards the latter end of which, it began to dwindle, and at laſt, *viz.* March, 1573, totally diſappeared, without any change of place in all that time.

Leovicius tells us of another ſtar appearing in the ſame conſtellation about the year 945, which reſembled that of 1572, and quotes another ancient obſervation, by which it appears, that a new ſtar was ſeen about the ſame place in 1264.

Dr. Keil takes thoſe to have been all the ſame ſtar: and he conjectures its period to be 150 years; but though it did not appear at the end of this period, this might be owing to its having different degrees of luſtre at different periods. Right aſc. in 1786, $0^h\,13'\,0''$. Declin. N. $62^\circ\,58'$. Greateſt and leaſt magn. 1—0.

Fabricius, in 1596, diſcovered another new ſtar, called the *ſtella mira,* or wonderful ſtar, in the neck of the Whale, which has been ſince found to appear and diſappear periodically, ſeven times in ſix years, continuing in the greateſt luſtre for fifteen days together; and is never quite extinguiſhed. Its courſe and motion are deſcribed by Bullialdus, in a treatiſe printed at Paris in 1667. R. aſc. in 1786, $2^h\,8'\,33''$. Decl. S. $3^\circ\,37'\,25''$. Greateſt and leaſt magn. 2—0. Period, determined by Caſſini, 334 days: ſeen by Mr. Goodricke of the 2d magnitude, Auguſt 9th, 1782, and by Mr. Pigott of the 8.9 magn. Dec. 30, 1782.

Dr. Herſchel has lately, *viz.* in the years 1777, 1778, 1779, 1780, made ſeveral obſervations on this ſtar, an account of which may be ſeen in the Phil. Tranſ. vol. lxx. part ii. art. 21. He makes its period $331^d\,10^h\,19'$.

The variations of Algol, or β Perſeus, were firſt obſerved by Montanari. In 1693, Maraldi could not perceive any change in its brightneſs; but in 1694 he ſaw its variation from the ſecond to the fourth magnitude. Its period was firſt diſcovered by Mr. Goodricke to be $2^d\,20^h\,48'\,56''$. He found that its brightneſs, at its minimum, is different in different periods; and Pigott perceived, that, at its maximum of brightneſs, it is ſometimes more luminous than α Perſei, and at other times leſs brilliant. R. aſc. 1786, $2^h\,54'\,19''$. Decl. N. $40^\circ\,6'\,55''$. Greateſt and leaſt magn. 2—4.

The 420th ſtar in Mayer's Catalogue, ſituated in the Lion, was found to be variable by M. Koch, being in February, 1782, of the ſeventh magnitude; in April, 1783, of the ninth; and in April, 1784, of the tenth. Mr. Pigott could not ſee it, and it muſt therefore have diſappeared. R. aſc. 1786, $9^h\,36'\,5''$. Decl. N. $12^\circ\,25'\,0''$. Greateſt and leaſt magn. 6—0.

Star in Hydra, as far eaſt of π as ψ is weſt of γ, the 30th Hydra of Hevelius, and probably the 1ſt of the Balance, according to Flamſtead, was diſcovered to be variable, in 1784, by Maraldi; and he made its period two years. According to Pigott, it is of the fourth magnitude at its full brightneſs, and for a fortnight ſuffers no perceptible change. It takes about ſix months to increaſe from the tenth to the fourth magnitude, and about the ſame time to return to the tenth; ſo that it may be regarded as inviſible to the naked eye during ſix months. R. aſc. 1786, $13^h\,18'\,4''$. Decl. S. $22^\circ\,9'\,38''$. Greateſt and leaſt magn. 4—0. Period 494 days.

In the year 1604, 17th October, Kepler, and ſeveral of his friends, ſaw a new ſtar near the heel of the right foot of Serpentarius, particularly bright and ſparkling; and took notice, that it was every moment changing into ſome of the colours of the rainbow, except when it was near the horizon, at which time it was generally white. It ſurpaſſed Jupiter in magnitude, but was eaſily diſtinguiſhed from it by the ſteady light of that planet. It began to diminiſh, and ceaſed to be viſible, October 18th, 1605, and has not been ſeen ſince that time; though Mr. Pigott has examined that part of the heavens with great care ſince the year 1782. R. aſc. $17^h\,18'\,0''$. Decl. S. $21^\circ\,10'\,30''$. Greateſt and leaſt magn. 1—0.

Simon Marius diſcovered another in Andromeda's girdle, in 1612 and 1613; though Bullialdus ſays, it had been ſeen before in the 15th century.

The variations and period of β Lyræ were diſcovered by Mr. Goodricke. R. aſc. $18^h\,42'\,11''$. Decl. N. $33^\circ\,7'\,46''$. Greateſt and leaſt magn. 3—4.5. Period, not accurately aſcertained, $6^d\,9^h$.

The new ſtar diſcovered by Don Anthelme in the Swan's head, on the 20th of June, 1670, ſoon reached the third magnitude, and, after ſeveral variations, diſappeared in 1672. It was obſerved of the ſixth magnitude, by Hevelius, in the years 1671, 1672; but ſince that time has not been ſeen, though Mr. Pigott muſt have detected it, if it had been of the tenth or eleventh magnitude. R. aſc. $19^h\,38'\,58''$. Decl. N. $26^\circ\,48'\,30''$. Greateſt and leaſt magn. 3—0.

The ſtar η Antinoi was diſcovered to be variable by Mr. Pigott, who alſo determined its period. It continues 40^h at its greateſt brightneſs, 30^h at its leaſt, 66^h on its decreaſe, and 36^h on its increaſe. R. aſc. $19^h\,41'\,34''$. Decl. N. $0^\circ\,28'\,14''$. Greateſt and leaſt magn. 3.4—5. Period $7^d\,4^h\,15'$.

The ſtar χ in the Swan's neck was diſcovered to be variable by Kirch, in 1686. Maraldi, Caſſini, and M. le Gentil, make its period 405 days; whence Pigott concludes that its period is variable, who ſtates that it continues a fortnight at its full brightneſs. It takes about $3\frac{1}{2}$ months to increaſe from the eleventh magnitude to its maximum brightneſs, and to decreaſe to the eleventh again; ſo that it may be regarded as inviſible for ſix months. At its greateſt luſtre, it is ſometimes of the fifth, and, at other times, of the ſeventh magnitude. R. aſc. $19^h\,42'\,21''$. Decl. N. $32^\circ\,22'\,58''$. Greateſt and leaſt magn. 5—0. Period $396^d\,21^h$.

The changeable ſtar near γ in the Swan's breaſt was obſerved by William Janſenius and Kepler in 1600: it became, in time, ſo ſmall as to be thought to have entirely diſappeared, until the years 1657, 1658, and 1659, when it recovered its former luſtre and magnitude; but it ſoon decayed. Pigott concludes, from the obſervations of the 17th century, that it continues about five years at its full brightneſs; that its luſtre decreaſes rapidly during two years; that it is inviſible to the naked eye during four years; and that it increaſes ſlowly during ſeven years. At the end of the year 1663, it was at its minimum brightneſs. From November, 1781, to 1786, Pigott always ſaw it of the ſixth magnitude; though he ſuſpects, that in 1785, 1786, it had rather decreaſed. R. aſc. $20^h\,9'\,54''$. Decl. N. $37^\circ\,22'\,37''$. Greateſt and leaſt magn. 3—0. Period 18 years.

The variation and period of δ Cephei were diſcovered by Mr. Goodricke, and the period has been confirmed by Mr. Pigott's obſervations. Its variations are not eaſily perceptible, unleſs at its minimum and maximum brightneſs. R. aſc. $22^h\,21'\,0''$. Decl. N. $57^\circ\,20'\,0''$. Greateſt and leaſt magn. 4.3—4.5. Period $5^d\,8^h\,37\frac{1}{2}'$.

The variation and period of the ſtar 64 or α Hercules were diſcovered by Dr. Herſchel, by comparing it with κ Ophiuchi. R. aſc. $17^h\,4'\,54''$. Decl. N. $14^\circ\,38'$. Period of variation $60\frac{1}{4}$ days.

The period and variations of a ſtar in Sobieſki's ſhield, having nearly the ſame right aſcenſion as the ſtar *l*, and ſituated about a degree farther ſouth, were diſcovered by Mr. Pigott, who has given the reſult of his obſervations in a table. R. aſc. in 1796, 18^h 36′ 38″. Decl. S. 5° 56′. Greateſt and leaſt magn. 5—7.8. Period 62 days.

The ſtar in the Northern Crown, ranked of the ſixth magnitude by Bayer, but omitted in Flamſtead's Catalogue, was ſuſpected by Mr. Pigott, in 1783, to be variable; and his ſuſpicions were confirmed in the ſpring of 1795, when it became inviſible. He ſaw it on the 20th of June in this year, of the 9.10th magnitude; and in ſix weeks afterwards, it attained its full brightneſs; and on the 11th of Auguſt, 1795, it was of the 6.7th magnitude, and ſo continued for about three weeks. In 3½ weeks it decreaſed to the 9.10th magnitude, and a few days afterwards it diſappeared. In April, 1796, it re-appeared; and on the 7th of May it reached the 9.10th magnitude, increaſing as it had done on the 20th of June, 1795. At its maximum brightneſs, it exhibited great unſteadineſs. It then increaſed, as before, till it reached the 7.8th magnitude; wavering between theſe two magnitudes till Auguſt, 1797. R. aſc. in 1796, 15^h 40′ 11″. Decl. N. 28° 49′ 30″. Greateſt and leaſt magn. 6.7—0. Period 10½ months.

The ſtars that are ſuppoſed to be variable are the following: *viz.* Hevelius's 6 Caſſiopeiæ; R. aſc. 0^h 23′ 16″. Decl. N. 60° 50′. Greateſt and leaſt magn. 7—0:——46 or ξ Andromedæ, ſuſpected to be different ſtars; R. aſc. 1^h 9′ 46″. Decl. N. 44° 24′. Greateſt and leaſt magn. 4.5—5.6:——Flamſtead's 50 or υ Andromedæ; R. aſc. 1^h 24′ 16″. Decl. N. 40° 20′ 15″. Greateſt and leaſt magn. 4.5—0:——Hevelius's 41 Andromedæ, probably the ſame with Tycho's Andromedæ; alſo, Flamſtead's 50, of the 4.5th magnitude; Flamſtead's τ, of the fifth magnitude; Flamſtead's 49 and 52, and Hevelius's 41, all three of the ſame brightneſs, are of the 5.6th magnitude. A ſtar between Hevelius's 41 and Flamſtead's 52 is rather leſs than the ſixth magnitude:——Tycho's 20 Ceti, probably χ in the Whale's belly, of the 4.5th magnitude, and of the ſame brightneſs as the three ψ Aquarii, which diſappeared in the time of Hevelius; R. aſc. 1^h 39′. Decl. S. 13° 20′. Greateſt and leaſt magn. 5—0:——Flamſtead's 55 Andromedæ, marked nebulous in his catalogue, obſerved to be a ſtar of the ſixth magnitude; R. aſc. 1^h 40′ 30″. Decl. N. 39° 40′ 3″. Greateſt and leaſt magn. 6—0:——σ or the 17th Eridani, according to Ptolemy and Ulugh Beigh, could not be ſeen by Flamſtead in 1691 and 1692; but in 1782, 1783, and 1784, Mr. Pigott obſerved in this place a ſtar of the ſeventh magnitude, without any variation of brightneſs; R. aſc. 2^h 42′. Decl. S. 9° 40′. Greateſt and leaſt magn. 4—0:——Flamſtead's 41 Tauri, the 26th of Ulugh Beigh, and the 43d of Tycho, ſuſpected by Caſſini to be new and variable, was ſeen by Ulugh Beigh and Tycho, and found by Mr. Pigott, in 1784 and 1785, to be of the fifth magnitude, as Hevelius made it, but of the ſixth magnitude, according to Flamſtead; R. aſc. 3^h 53′ 27″. Decl. N. 27° 0′ 39″. Greateſt and leaſt magn. 5—8:——The ſtar 2° 15′ N. of 53 Eridani, was believed by Caſſini to be a new ſtar, and was not viſible in 1664; but in 1784, Mr. Pigott obſerved it to be leſs than ω and *d*, brighter than A, and equal to ψ Eridani; R. aſc. 4^h 29′. Decl. S. 12° 30′. Greateſt and leaſt magn. 4—0:——Flamſtead's 47 Eridani was alſo ſuppoſed by Caſſini to be a new one; but in 1784 it appeared to Mr. Pigott leſs than 46 Eridani. R. aſc. 4^h 23′ 54″. Decl. S. 8° 41′ 40″. Greateſt and leaſt magn. 4—0:——The ſtar γ of the Great Dog is marked by Tycho, Bayer, Hevelius, and Flamſtead, as of the third magnitude: inviſible in 1670, according to Maraldi and Montanari, but in 1692 and 1693, it appeared of the fourth magnitude; obſerved by Mr. Pigott frequently ſince 1782, without the leaſt variation; always of the fourth magnitude, a little brighter than θ, and decidedly brighter than ι; made by La Caille of the fourth magnitude. R. aſc. 6^h 54′ 5″. Decl. S. 15° 19′ 36″. Greateſt and leaſt magn. 3—0:——Pollux, or β Gemini, was undoubtedly brighter in 1783, 1784, and 1785, than Caſtor; both made by Hevelius of the ſecond magnitude: Flamſtead makes Caſtor of the firſt, and Pollux of the ſecond magnitude: La Caille makes Caſtor of the 1.2d, and Pollux of the 2.3d magnitude: and Bradley makes them both of the firſt magnitude. R. aſc. 7^h 32′ 11″. Decl. N. 28° 31′ 38″. Greateſt and leaſt magn. 1—3:——The ſtar ξ Leonis is marked by Tycho, Bayer, Flamſtead, Mayer, and Bradley, of the fourth magnitude; could ſcarcely be ſeen by Maraldi and Montanari in 1693; always ſeen in 1783, 1784, and 1785, of the fifth magnitude, leſs than A and π, and perhaps rather brighter than *b* and ω Leonis. R. aſc. 9^h 20′ 4″. Decl. N. 12° 14′ 23″. Greateſt and leaſt magn. 5.6—0:——The ſtar ψ Leonis is ſaid to have diſappeared in 1667, when it was ſeen by Montanari; obſerved by Maraldi in 1691, when it was very ſmall; from 1784 to 1786, always ſeen by Pigott of the 5.6th magnitude, leſs than ω, and brighter than *i*, Flamſtead's 46th; made by Hevelius of the fifth, and by Flamſtead of the ſixth magnitude. R. aſc. 9^h 32′ 3″. Decl. N. 14° 59′ 36″. Greateſt and leaſt magn. 5.6—0:——The ſtar 25 Leonis was found by Mr. Pigott to be miſſing in 1783, nor could he ſee it in 1784 and 1785. R. aſc. 9^h 46′ 8″. Decl. N. 12° 20′ 36″. Greateſt and leaſt magn. 6.7—0:——Bayer's *i* Leonis and Tycho's 16 Leonis was inviſible in 1709; and could not be ſeen by Pigott in 1785; nor is it the *i* Leonis of other catalogues. R. aſc. 9^h 52′ 30″. Decl. N. 15° 30′. Greateſt and leaſt magn. 6—0:——δ of the Great Bear is marked of the ſecond magnitude by Tycho and the prince of Heſſe; but Hevelius, La Caille, and Bradley, mark it of the third. From 1783 to 1786 it appeared to Pigott as a bright fourth magnitude, rather leſs than ι, equal to α, and rather brighter than κ Draconis: Flamſtead makes it of the 2.3d magnitude. R. aſc. 12^h 4′ 45″. Decl. N. 58° 13′ 24″. Greateſt and leaſt magn. 2—4:——The ſtar *n* Virginis, though not in the charts of Bayer, was obſerved by Ricciolus; was not ſeen by Flamſtead on the 27th of January, 1680, though he muſt have obſerved it on the 12th of May 1677, and ſome years afterwards, as it is in his catalogue; obſerved frequently in 1784 and 1785, by Pigott; but it always appeared of the ſixth magnitude, as it is marked by Flamſtead; by Bradley it is of the fifth magnitude. R. aſc. 12^h 7′ 43″. Decl. N. 0° 24′ 16″. Greateſt and leaſt magn. 6—0:——Bayer's ſtar of the ſixth magnitude, 1° S. of γ Virginis, could not be ſeen by Maraldi, and looked for in vain by Pigott in May, 1785. R. aſc. 12^h 53′. Decl. S. 10°. Greateſt and leaſt magn. 6—0:——The ſtar in the Virgin's northern thigh is marked by Ricciolus as of the 6th magnitude; could not be ſeen by Maraldi in 1709, nor by Pigott in 1785. R. aſc. 13° 29′+. Decl. S. 0° 30′. Greateſt and leaſt magn. 6—0:——91 or 92 Virginis, the firſt ſuppoſed by Pigott to be miſſing in 1785; the other is of the 6.7th magnitude. R. aſc. 13^h 43′ 43″. Decl. N. 2° 5′ 50″. Greateſt and leaſt magn. 6—0:——The ſtar α Draconis is at preſent only of the 4th magnitude, though Hevelius, Flamſtead, and Bradley, mark it of the third; Pigott and Herſchel think it to be variable; La Caille marks it of the third magnitude. R. aſc. 13^{h}58° 36′. Decl. N. 65° 24′ 8″. Greateſt and leaſt magn. 2—4:——Bayer's ſtar in the Weſt Scales of Libra, could not be found by Maraldi, nor by Pigott in 1784 and 1785.

R. aſc. 14° 53′ 30″. Decl. S. 13° 26′. Greateſt and leaſt magn. 4—7 :——Ptolemy's and Ulugh Beigh's N° 6 of the unformed ſtars in Libra, is marked of the fourth magnitude, and nevertheleſs does not appear in any modern catalogue; in 1785, Mr. Pigott often obſerved a ſtar of the ſeventh magnitude very near its place, rather leſs than Flamſtead's 41. R. aſc. 15^h 29′ +. Decl. S. 20° 30′. Greateſt and leaſt magn. 4—7 :——The ſtar κ Libræ is marked by Tycho and Bayer as of the fourth magnitude; Hevelius ſays that it had diſappeared: in the years 1783, 1784, and 1785, Pigott always found it of the fifth magnitude; but Flamſtead marks it of the fourth. R. aſc. 15^h 29′ 39″. Decl. S. 19° 58′ 27″. Greateſt and leaſt magn. 4—5 :——Tycho's 11 Libræ could not be found by Hevelius and Pigott; the latter thinks that it never exiſted, and that it is the κ, with an error of 2° in longitude. R. aſc. 15^h 37′ 30″. Decl. S. 19° 30′. Greateſt and leaſt magn. 4—0 :——The ſtar 33 Serpentis was found to be miſſing in 1784 and 1785, by Pigott. R. aſc. 15^h 38′. Decl. N. 17° 14′. Greateſt and leaſt magn. 6—0 :——Bayer's ſtar, near ε of the Great Bear, could not be ſeen by Caſſini; nor could Pigott find any ſtar near the ε brighter than the 7.8th magnitude. R. aſc. 16^h 15′. Decl. N. 82° 45′. Greateſt and leaſt magn. 6—0 :——The ſtar ς, or Ptolemy's and Ulugh Beigh's 14th of Ophiuchus, or Flamſtead' 36th, is ſaid to have diſappeared before 1695; could not be found by Hevelius; but Pigott found it in 1784 and 1785 of the 4.5th magnitude, much brighter than 39, rather brighter than 51 and 58, and leſs than 44. R. aſc. 17^h 2′ 14″. Decl. S. 26° 15′ 37″. Greateſt and leaſt magn. 4—0 :——Ptolemy's 13th Ophiuchi. R. aſc. 17^h 18′ +. Decl. S. 20° 35′. Greateſt and leaſt magn. 4—0 :——Ptolemy's 18th Ophiuchi. R. aſc. 17^h 22′. Decl. S. 24° 10′. Greateſt and leaſt magn. 5—0. Theſe two laſt-mentioned ſtars ſeem to have diſappeared; however, Mr. Pigott thinks that the 13th Ophiuchi is Flamſtead's 40th, and that the 18th Ophiuchi ſhould be marked with north inſtead of ſouth latitude, which would make it coincide nearly with Flamſtead's 58th :——The ſtar σ Sagittarii is thought by Dr. Herſchel and Mr. Pigott to be variable; in 1783, 1784, and 1785, he obſerved it to be of the 2.8th magnitude, and brighter than π Sagittarii. Hevelius makes it of the fourth, and La Caille of the 2.3d magnitude. R. aſc. 18^h 42′. Decl. S. 26° 32′ 34″. Greateſt and leaſt magn. 2—4 :——The ſtar θ Serpentis was obſerved by Tycho, Bayer, Hevelius, and Flamſtead, to be of the third magnitude; according to Montanari, it was of the fifth; it was frequently obſerved in 1783, 1784, and 1785, by Pigott, without any perceptible change of luſtre, always of the fourth magnitude, leſs than δ Aquilæ and P Ophiuchi; La Caille makes it of the 4.3d magnitude. R. aſc. 18^h 45′ 35″. Decl. N. 3° 56′ 36″. Greateſt and leaſt magn. 4—5 :——Tycho's 27 Capricorni could not be ſeen by Hevelius nor by Pigott. R. aſc. 21^h 41′ 0″. Decl. S. 14° 28′ 0″. Greateſt and leaſt magn. 6—0 :——Tycho's 22 Andromedæ, at the end of the chain, was, as Caſſini obſerves, ſo ſmall, that it could ſcarcely be ſeen: Pigott could find no ſtar in its place near the two π Cygni, in 1784 and 1785. R. aſc. 21^h 43′ 30″. Decl. N. 49° 15′. Greateſt and leaſt magn. 4—0 :——Tycho's 19th Aquarii was marked as miſſing by Hevelius, nor could Flamſtead ſee it with his naked eye; Pigott is confident that it is the ſame with Flamſtead's 56th, marked *f* by Bayer, from which it is only $1\frac{1}{2}$° diſtant. R. aſc. 22^h 25′. Decl. S. 15° 55′ 0″. Greateſt and leaſt magn. 6—0 :——The ſtar ο Andromedæ is, according to Pigott, leſs than σ Cephei, equal to ζ Caſſiopeiæ, or perhaps brighter than it, and brighter than λ, κ, or ι Andromedæ. R. aſc. 22^h 52′ 6″. Decl. N. 41° 10′ 45″. Greateſt and leaſt magn. 4—6 :——La Caille's 483 Aquarii was found by Pigott miſſing in 1778, nor could he ſee it in 1783 or 1784. R. aſc. 22^h 55′ 40″. Decl. S. 8° 50′ 45″.

The following 13 ſtars are ranked by Dr. Herſchel among thoſe that are loſt, or have undergone ſome great change; *viz.* 80 and 81 Hercules; 71 Hercules; 55 Hercules; 56 Cancer; 19 Perſeus; 108 Piſces; 73 and 74 Cancer; 8 Hydræ; 26 Cancer; 62 Orion; 34 Berenice's Hair; and 19 Berenice's Hair. The following are reckoned by Dr. Herſchel among thoſe that have undergone a change of magnitude ſince the time of Flamſtead: *viz.* α Draconis, α Ceti, ζ Serpentis, η in the Swan, the 2 of the Great Bear, η Bootes, ι Dolphin, β Triangle, γ Eagle, σ Sagittarius, δ of the Great Dog, κ Serpent, κ Serpentarius, β of the Little Horſe, δ Dolphin, ε Bootes, δ in the Arrow, δ in the Great Bear, α Great Bear, 1ſt and 2d Hydræ, γ Lyræ, 31ſt and 34th of the Dragon, 44 Cancer, 96 Tauri, 62 Aries, 12 and 14 Lynx, 38 Perſeus, θ Perſeus, δ Unicorn, 23 Gemini, 26 Orion, and ξ Lion. The following are marked by Dr. Herſchel among the ſtars that have recently become viſible; *viz.* a ſtar in the end of the Lizard's tail, of the 4.5th magnitude; the ſtar of the eighth magnitude following τ Perſeus, probably new; a ſtar near the head of Cepheus, not given by Flamſtead; a conſiderable ſtar in a direction from the 68th to the 61ſt Gemini, not in Flamſtead's catalogue; a ſtar of conſiderable brightneſs, preceding the firſt of the Little Horſe, not given by Flamſtead; a conſiderable ſtar, following the firſt of the Sextant, and another following the 7th, not in Flamſtead's catalogue; a remarkable ſtar between β and δ Hydra, not given by Flamſtead; a ſtar nearly 1° 30′ N. following δ Hercules, in the direction of δ and ν, and of the 4.5th magnitude, not given by Flamſtead; a ſtar of the 6th magnitude, about 3° S. preceding γ Bootes, and another of the ſame ſize, preceding λ, not obſerved by Flamſtead. Phil. Tranſ. for 1783, vol. lxxiii. p. 247, &c.

From the old catalogues, it is certain that many of the ancient ſtars are not now viſible: this has been particularly remarked with regard to the Pleiades: and it is equally certain, as we have now ſhewn, that ſome have become viſible.

M. Montanari, in his letter to the Royal Society in 1670, obſerves, that there are now wanting in the heavens two ſtars of the ſecond magnitude, in the ſtern of the ſhip Argo and its yard, which had been ſeen till the year 1664. When they firſt diſappeared is not known; but he aſſures us there was not the leaſt glimpſe of them in 1668. He adds he has obſerved many more changes in the fixed ſtars, even to the number of a hundred.

Many other changes in the ſtars have been taken notice of by Caſſini, Maraldi, and other obſervers. See Gregory's Aſtr. lib. ii. prop. 30, and the preceding part of this article.

As none of theſe ſtars could ever be perceived to have tails, it is plain they could not be comets; eſpecially as they had no parallax, even when largeſt and brighteſt. It is not improbable that the periodical ſtars have vaſt cluſters of dark ſpots, and very ſlow rotations on their axes, by which means they muſt diſappear when the ſide covered with ſpots is turned towards us. And as for thoſe which break out on a ſudden with ſuch luſtre, theſe may, perhaps, be ſuns whoſe fuel is almoſt ſpent, and again ſupplied by ſome of their comets falling upon them, and occaſioning an uncommon blaze and ſplendour for ſome time; which has been conjectured to be one uſe of the cometary part of any ſyſtem.

M. Maupertuis, in his Diſſertation on the Figures of the

Celeſtial Bodies (p. 61—63.), is of opinion, that ſome ſtars, by their prodigious ſwift rotation on their axes, may not only aſſume the figures of oblate ſpheroids, but that by the great centrifugal force ariſing from ſuch rotations, they may become of the figures of mill-ſtones, or be reduced to flat circular planes, ſo thin, as to be quite inviſible when their edges are turned towards us, as Saturn's ring is in ſuch poſition. But when very eccentric planets or comets go round any flat ſtar in orbits much inclined to its equator, the attraction of the planets or comets in their perihelions muſt alter the inclination of the axes of that ſtar; on which account it will appear more or leſs large and luminous, as its broad ſide is more or leſs turned towards us. And thus he imagines we may account for the apparent changes of magnitude and luſtre of thoſe ſtars, and likewiſe for their appearing and diſappearing.

Hevelius (Cometograph. p. 380.) apprehends, that the ſun and ſtars are ſurrounded with atmoſpheres, and that, whirling round their axes with great rapidity, they throw off great quantities of matter into thoſe atmoſpheres, and thereby cauſe great changes in them; and that thus it may come to paſs, that a ſtar, which when its atmoſphere is clear, ſhines out with great luſtre, may at another time, when it is full of clouds and thick vapours, appear greatly diminiſhed in brightneſs and magnitude, or even become quite inviſible.

The periodical variation in the light of the ſtars has alſo been aſcribed to the interpoſition of the planets which circulate around them; but it is by no means probable, that theſe planets, even if they do exiſt, are ſufficiently large to obſtruct any large portion of their light. Even when ſeen from the earth, the light of our own ſun is not ſenſibly impaired, when Mercury and Venus are paſſing over his diſc.

The ingenious Mr. Pigott has ventured a ſtep farther than any of his predeceſſors in this branch of aſtronomy. In his inveſtigation of the phenomena exhibited by the variable ſtar of Sobieſki's ſhield, the periodical changes of which are affected by very ſingular anomalies, he ſuppoſes, that the greater part of its diſc is unenlightened; and that a few luminous ſpots, placed at certain intervals, produce, by the rotation of the ſtar, all the variations which have been obſerved. Mr. Pigott ſuppoſes, that the body of the ſtars is dark and ſolid; that their rotation on their axes is regular; and that the ſurrounding medium is occaſionally generating and abſorbing its luminous particles, by a proceſs ſimilar to what Dr. Herſchel ſuppoſes is going on in the atmoſphere of the ſun. He imagines, that theſe luminous particles are ſparingly diſperſed in the atmoſphere of the variable ſtar of Sobieſki, from the circumſtance of its diminiſhing even to the ninth magnitude; and as the duration of its full luſtre continues only about 9½ days, while it performs a complete rotation in 62 days, he conſiders the luminous ſpots to be ſomewhat circular, and of no great extent. Since this ſmall portion of light may naturally be ſuppoſed to diminiſh and finally diſappear, Mr. Pigott imagines, that this may have been the cauſe of the diſappearance of the new ſtars of 1572 and 1604. Hence he concludes, that there are others which have never ſhewn a glimpſe of brightneſs; and that there are "primary inviſible bodies, or unenlightened ſtars, that have ever remained in eternal darkneſs." Following out this notion, Mr. Pigott conceives, that cluſters of theſe dark bodies may be found, and by intercepting "all more diſtant rays," may appear like dark ſpaces in the heavens, ſimilar to what has been obſerved in the ſouthern hemiſphere.

Stars, *As for the Nature of the fixed*, their immenſe diſtance leaves us greatly at a loſs about it. What we can gather for certain from their phenomena is as follows:

1. That the fixed ſtars are greater than our earth: becauſe, if that was not the caſe, they could not be viſible at ſuch an immenſe diſtance.

2. The fixed ſtars are farther diſtant from the earth than the fartheſt of the planets. For we frequently find the fixed ſtars hid behind the moſt diſtant of the planets: and beſides, they are ſuppoſed to have no parallax, which the planets have.

3. The fixed ſtars ſhine with their own light; for they are much farther from the ſun than the remoteſt planet, and appear much ſmaller; but ſince, notwithſtanding this, they are found to ſhine much brighter than ſuch planet, it is evident they cannot borrow their light from the ſame ſource as that does, *viz.* the ſun; but ſince we know of no other luminous body beſide the ſun, whence they might derive their light, it follows, that they ſhine with their own native light.

Beſides, it is known, that the more a teleſcope magnifies, the leſs is the aperture through which the ſtar is ſeen; and, conſequently, the fewer rays it admits into the eye. Now ſince the ſtars appear leſs in a teleſcope which magnifies two hundred times, than they do to the naked eye, inſomuch that they ſeem to be only indiviſible points, it proves at once that the ſtars are at immenſe diſtances from us, and that they ſhine by their own proper light. If they ſhone by borrowed light, they would be as inviſible without teleſcopes as the ſatellites of Jupiter are; for theſe ſatellites appear bigger, when viewed with a good teleſcope, than the largeſt fixed ſtars do. Hence,

1. We deduce, that the fixed ſtars are ſo many ſuns; for they have all the characters of ſuns.

2. That, in all probability, the ſtars are not ſmaller than our ſun.

3. That it is highly probable, that each ſtar is the centre of a ſyſtem, and has planets or earths revolving round it, in the ſame manner as round our ſun, *i. e.* it has opaque bodies illuminated, warmed, and cheriſhed by its light. As we have incomparably more light from the moon than from all the ſtars together, it is abſurd to imagine that the ſtars were made for no other purpoſe than to caſt a faint light upon the earth; eſpecially ſince many more require the aſſiſtance of a good teleſcope to find them out than are viſible without that inſtrument. Our ſun is ſurrounded by a ſyſtem of planets and comets, all which would be inviſible from the neareſt fixed ſtar; and from what we already know of the immenſe diſtance of the ſtars, it is eaſy to prove, that the ſun, ſeen from ſuch a diſtance, would appear no bigger than a ſtar of the firſt magnitude.

From all this it is highly probable, that each ſtar is a ſun to a ſyſtem of worlds moving round it, though unſeen by us; eſpecially as the doctrine of a plurality of worlds is rational, and greatly manifeſts the power, wiſdom, and goodneſs of the great Creator.

How immenſe, then, does the univerſe appear! Indeed, it muſt either be infinite, or infinitely near it.

Kepler, it is true, denies that each ſtar can have its ſyſtem of planets as our's has; and takes them all to be fixed in the ſame ſurface or ſphere; urging, that were one twice or thrice as remote as another, it would appear twice or thrice as ſmall, ſuppoſing their real magnitudes equal; whereas there is no difference in their apparent magnitudes, juſtly obſerved, at all. But to this we oppoſe, that Huygens has not only ſhewn that fires and flames are viſible at diſtances where other bodies, comprehended under equal angles, diſappear; but it ſhould likewiſe ſeem, that the optic theorem about the apparent diameters of objects, being reciprocally proportional to their diſtances from the eye, does only hold while the diameter of the object has ſome ſenſible ratio to its diſtance.

As for periodical ſtars, &c. ſee *Changes*, &c. *of* Stars, *ſupra.*

Stars, *Motion of the.* The fixed ſtars have two kinds of apparent motion; one called the *firſt, common,* or *diurnal* motion, ariſing from the earth's motion round its axis: by this they ſeem to be carried along with the ſphere, or firmament, (in which they appear fixed,) round the earth, from eaſt to weſt, in the ſpace of twenty-four hours.

The other, called the *ſecond,* or *proper* motion, is that by which they appear to go backwards from weſt to eaſt, round the poles of the ecliptic, with ſuch ſlowneſs, as not to deſcribe above a degree of their circle in the ſpace of 72 years, or 50 ſeconds in a year.

This apparent motion is owing to the receſſion of the equinoctial points, which is 50 ſeconds of a degree in a year backward, or contrary to the order of the ſigns of the zodiac.

Some have imagined, but it is unknown on what grounds, that when they are got round to the points whence they firſt departed, nature will have finiſhed her courſe, and the ſtars having performed their career, the heavens will remain at reſt; unleſs the Being, who firſt gave them motion, appoint them to begin another circuit.

On the footing of this calculation, the world ſhould laſt about 30,000 years, according to Ptolemy; 25,816, according to Tycho; 25,920, according to Riccioli; and 24,800, according to Caſſini.

In conſequence of this ſecond motion, the longitude of the ſtars will be always increaſing.

Thus, *e. gr.* the longitude of Cor Leonis was found by Ptolemy, A.D. 138, to be 2° 30′; in 1115, it was obſerved by the Perſians to be 17° 30′; in 1364, by Alphonſus, 20° 40′; in 1586, by the prince of Heſſe, 24° 11′; in 1601, by Tycho, 24° 17′; and in 1690, by Mr. Flamſtead, 25° 31′ 20″; whence the proper motion of the ſtars, according to the order of the ſigns in circles parallel to the ecliptic, is eaſily inferred.

It was Hipparchus who firſt ſuſpected this motion, upon comparing the obſervations of Timocharis and Ariſtyllus with his own. Ptolemy, who lived three centuries after Hipparchus, demonſtrated the ſame by undeniable arguments.

Tycho Brahe makes the increaſe of longitude in a century 1° 25′; Copernicus, 1° 23′ 40″ 12‴; Flamſtead and Ricciolus, 1° 23′ 20″; Bullialdus, 1° 24′ 54″; Hevelius, 1° 24′ 46″ 50‴; whence, with Flamſtead, the annual increaſe of the longitudes of the fixed ſtars may be well fixed at 50″.

From theſe data, the increaſe of the longitude of a ſtar for any given time is eaſily had; and hence the longitude of a ſtar for any given year being given, its longitude for any other year is readily found: *e. gr.* the longitude of Sirius, in Mr. Flamſtead's tables, for the year 1690, being 9° 49′ 1″; its longitude for the year 1724 is found by multiplying the interval of time, *viz.* 34 years, by 50″; the product 1700″, or 28′ 20″, added to the given longitude, will give the longitude required, 10° 17′ 21″. By means of this correction, applied as the caſe requires, the longitudes of the ſtars, tranſcribed from any tables, may be adapted to the preſent or any given time.

The principal phenomena of the fixed ſtars, ariſing from their common and proper motion, beſides their longitude, are their altitudes, right aſcenſions, declinations, occultations, culminations, riſings, and ſettings. See Altitude, Ascension, Declination, and Occultation.

Some have ſuppoſed that the latitudes of the ſtars are invariable; but this ſuppoſition is founded on two aſſumptions, which are both controverted among aſtronomers: one is, that the orbit of the earth continues unalterably in the ſame plane, and conſequently that the ecliptic is invariable, the contrary of which is now very generally allowed. See Ecliptic.

The other aſſumption is, that the ſtars are ſo fixed as to keep their places immoveably. Ptolemy, Tycho, and others, comparing the obſervations of ancient aſtronomers with their own, have adopted this opinion. But from the reſult of the compariſon of our beſt modern obſervations, with ſuch as were formerly made with any tolerable degree of exactneſs, there appears to have been a real change in the poſition of ſome of the fixed ſtars, with reſpect to each other; and ſeveral ſtars of the firſt magnitude have already been obſerved, and others ſuſpected to have a proper motion of their own.

Dr. Halley (Phil. Tranſ. N° 355, or Jones's Abr. vol. iv. p. 225.) has obſerved, that the Bull's eye, Sirius, and Arcturus, are now found to be about half a degree more ſoutherly than the ancients reckoned them: that this difference cannot ariſe from the errors of the tranſcribers, becauſe the declination of the ſtars, ſet down by Ptolemy, as obſerved by Timocharis, Hipparchus, and himſelf, ſhew their latitudes given by him are ſuch as thoſe authors intended; and it is ſcarcely to be believed, that thoſe three obſervers could be deceived in ſo plain a matter. To this he adds, that the bright ſtar in the ſhoulder of Orion has, in Ptolemy, almoſt a whole degree more ſoutherly latitude than at preſent: that an ancient obſervation, made A.D. 509, at Athens, as Bullialdus ſuppoſes, of an appulſe of the moon to the Bull's eye, ſhews that ſtar to have had leſs latitude at that time than it now has; that as to Sirius, it appears by Tycho's obſervations, that he found him 4½ more northerly than he is at this time. All theſe obſervations, compared together, ſeem to favour an opinion, that ſome of the ſtars have a proper motion of their own, which changes their places in the ſphere of heaven: this change of place, as Dr. Halley obſerves, may ſhew itſelf in ſo long a time as 1800 years, though it be entirely imperceptible in the ſpace of one ſingle century; and it is likely to be ſooneſt diſcovered in ſuch ſtars as thoſe juſt now mentioned, becauſe they are all of the firſt magnitude, and may, therefore, probably be ſome of the neareſt to our ſolar ſyſtem. Arcturus, in particular, affords a ſtrong proof of this: for if its preſent declination be compared with its place as determined either by Tycho or Flamſtead, the difference will be found to be much greater than what can be ſuſpected to ariſe from the uncertainty of their obſervations. See Arcturus, and Mr. Hornſby's Inquiry into the Quantity and Direction of the proper Motion of Arcturus, Phil. Tranſ. vol. lxiii. part i. p. 93, &c.

Upon the whole, we have reaſon to conclude, that there is not, ſtrictly ſpeaking, any *fixed* ſtar in the heavens; and to admit the general motion of all the ſtarry ſyſtems, and conſequently of the ſolar one among the reſt.

For an account of Dr. Bradley's obſervations, ſee the ſequel of this article.

Dr. Herſchel has alſo lately obſerved, that the diſtance of the two ſtars forming the double ſtar γ Draconis, Fl. 24 and 25, is 54″ 48‴, and their poſition 44° 19′ N. preceding. Whereas, from the right aſcenſion and declination of theſe ſtars in Flamſtead's Catalogue, their diſtance, in his time, appears to have been 1′ 11″.418, and their poſition 44° 23′ N. preceding. Hence he infers, that as the difference in the diſtance of theſe two ſtars is ſo conſiderable, we can hardly account for it, otherwiſe than by admitting a proper motion in one or the other of the ſtars, or in our ſolar ſyſtem: moſt probably, he ſays, neither of the three is at reſt. He alſo ſuſpects a proper motion in one of the double ſtars in cauda Lyncis media, Fl. 38, and in ο Ceti, Fl. 68. Phil. Tranſ. vol. lxxii. part i. p. 117. 143. 150.

It is reaſonable to expect, that other inſtances of the like kind muſt alſo occur among the great number of viſible ſtars, becauſe their relative poſitions may be altered by various means. For if our own ſolar ſyſtem be conceived to change its place with reſpect to abſolute ſpace, this might, in proceſs of time, occaſion an apparent change in the angular diſtances of the fixed ſtars; and in ſuch a caſe, the places of the neareſt ſtars being more affected than of thoſe that are very remote, their relative poſition might ſeem to alter, though the ſtars themſelves were really immoveable: and *vice verſâ*, we may ſurmiſe, from the obſerved motion of the ſtars, that our ſun, with all his planets and comets, may have a motion towards ſome particular part of the heavens, on account of a greater quantity of matter collected in a number of ſtars and their ſurrounding planets there ſituated, which may perhaps occaſion a gravitation of our whole ſolar ſyſtem towards it. If this ſurmiſe ſhould have any foundation, as Dr. Herſchel obſerves, *ubi ſupra*, p. 103, it will ſhew itſelf in a ſeries of ſome years; as from that motion will ariſe another kind of hitherto unknown parallax (ſuggeſted by Mr. Michell, Phil. Tranſ. vol. lvii. p. 252.), the inveſtigation of which may account for ſome part of the motions already obſerved in ſome of the principal ſtars; and for the purpoſe of determining the direction and quantity of ſuch a motion, accurate obſervations of the diſtance of ſtars that are near enough to be meaſured with a micrometer, and a very high power of teleſcopes, may be of conſiderable uſe, as they will undoubtedly give us the relative places of thoſe ſtars to a much greater degree of accuracy than they can be had by tranſit inſtruments or ſectors, and thereby much ſooner enable us to diſcover any apparent change in their ſituation, occaſioned by this new kind of ſyſtematical parallax, if we may ſo expreſs the change ariſing from the motion of the whole ſolar ſyſtem. For an account of Dr. Herſchel's theory of the annual parallax of double ſtars, with the method of computing from thence what is generally called the parallax of the fixed ſtars, or of ſingle ſtars of the firſt magnitude, ſuch as are neareſt to us, ſee the preceding part of this article, under *Diſtance of the* STARS.

On the other hand, if our ſyſtem be at reſt, and any of the ſtars really in motion, this might likewiſe vary their apparent poſitions; and the more ſo, the nearer they are to us, or the ſwifter their motions are, or the more proper the direction of the motion is to be rendered perceptible by us. Since then the relative places of the ſtars may be changed from ſuch a variety of cauſes, conſidering the amazing diſtance at which it is certain ſome of them are placed, it may require the obſervations of many ages to determine the laws of the apparent changes even of a ſingle ſtar; much more difficult, therefore, muſt it be to ſettle the laws relating to all the moſt remarkable ſtars.

When the cauſes which affect the places of all the ſtars in general are known, ſuch as the preceſſion, aberration, and nutation; it may be of ſingular uſe to examine nicely the relative ſituations of particular ſtars, and eſpecially of thoſe of the greateſt luſtre, which, it may be preſumed, lie neareſt to us, and may therefore be ſubject to more ſenſible changes, either from their own motion, or from that of our ſyſtem. And if at the ſame time that the brighter ſtars are compared with each other, we likewiſe determine the relative poſitions of ſome of the ſmalleſt that appear near them, whoſe places can be aſcertained with ſufficient exactneſs, we may perhaps be able to judge to what cauſe the change, if any be obſervable, is owing. The uncertainty that we are at preſent under, with reſpect to the degree of accuracy with which former aſtronomers could obſerve, makes us unable to determine ſeveral things relating to this ſubject; but the improvements which have of late years been made in the methods of taking the places of the heavenly bodies are ſo great, that a few years may hereafter be ſufficient to ſettle ſome points, which cannot now be ſettled, by comparing even the earlieſt obſervations with thoſe of the preſent age.

The firſt perſon who pointed out the method of inveſtigating the parallax of the ſtars, by taking the diſtances from the zenith of thoſe that paſs very near it, was Galileo. The execution of this method was alſo attempted by Hooke, Flamſtead, Molyneux, and Bradley. See *Diſtance of the* STARS, *ſupra*.

Dr. Hooke communicated ſeveral obſervations on the apparent motions of the fixed ſtars; and as this was a matter of great importance in aſtronomy, ſeveral of the learned were deſirous of verifying and confirming his obſervations. An inſtrument was accordingly contrived by Mr. George Graham, and executed with ſurpriſing exactneſs.

With this inſtrument the ſtar γ, in the conſtellation Draco, was frequently obſerved by Meſſrs, Molyneux, Bradley, and Graham, in the years 1725, 1726; and the obſervations were afterwards repeated by Dr. Bradley with an inſtrument contrived by the ſame ingenious perſon, Mr. Graham, and ſo exact, that it might be depended on to half a ſecond. The reſult of theſe obſervations was, that the ſtar did not always appear in the ſame place, but that its diſtance from the zenith varied; and that the difference of the apparent places of Themis, the third ſatellite of Jupiter, amounted to 21 or 22 ſeconds. Similar obſervations were made on other ſtars, and a like apparent motion was found in them, proportional to the latitude of the ſtar. This motion was by no means ſuch as was to have been expected, as the effect of a parallax; and it was ſome time before any way could be found of accounting for this new phenomenon. At length Dr. Bradley reſolved all its variety, in a ſatisfactory manner, by the motion of light and the motion of the earth compounded together. See LIGHT, and Phil. Tranſ. N° 406. p. 364, or Abr. vol. vi. p. 149, &c.

Our excellent aſtronomer, Dr. Bradley, had no ſooner diſcovered the cauſe, and ſettled the laws of the aberration of the fixed ſtars, than his attention was again excited by another new phenomenon, *viz.* an annual change of declination in ſome of the fixed ſtars, which appeared to be ſenſibly greater than a preceſſion of the equinoctial points of $50''$ in a year, the mean quantity now uſually allowed by aſtronomers, would have occaſioned.

This apparent change of declination was obſerved in the ſtars near the equinoctial colure, and there appearing at the ſame time an effect of a quite contrary nature in ſome ſtars near the ſolſtitial colure, which ſeemed to alter their declination leſs than a preceſſion of $50''$ required, Dr. Bradley was thereby convinced, that all the phenomena in the different ſtars could not be accounted for merely by ſuppoſing that he had aſſumed a wrong quantity for the preceſſion of the equinoctial points. He had alſo, after many trials, ſufficient reaſon to conclude, that theſe ſecond unexpected deviations of the ſtars were not owing to any imperfection of his inſtruments. At length, from repeated obſervations, he began to gueſs at the real cauſe of theſe phenomena.

It appeared from the doctor's obſervations, during his reſidence at Wanſtead, from the year 1727 to 1732, that ſome of the ſtars near the ſolſtitial colure had changed their declinations $9''$ or $10''$ leſs than a preceſſion of $50''$ would have produced; and, at the ſame time, that others near the equinoctial colure had altered theirs about the ſame quantity more than a like preceſſion would have ocoaſioned; the north pole of the equator ſeeming to have approached the ſtars which come to the meridian with the ſun about the vernal equinox and the winter ſolſtice; and to have receded from thoſe which come to the meridian with the ſun about the autumnal equinox and the ſummer ſolſtice.

From the conſideration of theſe circumſtances, and the ſituation of the aſcending node of the moon's orbit when he firſt began to make his obſervations, he ſuſpected that the moon's action upon the equatorial parts of the earth might produce theſe effects. For if the preceſſion of the equinox be, according to ſir Iſaac Newton's principles, cauſed by the actions of the ſun and moon upon thoſe parts; the plane of the moon's orbit being, at one time, above ten degrees more inclined to the plane of the equator than at another, it was reaſonable to conclude, that the part of the whole annual preceſſion which ariſes from her action, would, in different years, be varied in its quantity; whereas the plane of the ecliptic, in which the ſun appears, keeping always nearly the ſame inclination to the equator, that part of the preceſſion which is owing to the ſun's action, may be the ſame every year; and from hence it would follow, that although the mean annual preceſſion, proceeding from the joint actions of the ſun and moon, were 50″; yet the apparent annual preceſſion might ſometimes exceed, and ſometimes fall ſhort of that mean quantity, according to the various ſituations of the nodes of the moon's orbit.

In the year 1727, the moon's aſcending node was near the beginning of Aries, and conſequently her orbit was as much inclined to the equator as it can at any time be; and then the apparent annual preceſſion was found, by the doctor's firſt year's obſervations, to be greater than the mean; which proved, that the ſtars near the equinoctial colure, whoſe declinations are moſt of all affected by the preceſſion, had changed theirs above a tenth part more than a preceſſion of 50″ would have cauſed. The ſucceeding year's obſervations proved the ſame thing; and in three or four years time the difference became ſo conſiderable, as to leave no room to ſuſpect it was owing to any imperfection either of the inſtrument or obſervation.

But ſome of the ſtars that were near the ſolſtitial colure having appeared to move, during the ſame time, in a manner contrary to what they ought to have done, by an increaſe of the preceſſion; and the deviations in them being as remarkable as in the others; it was evident that ſomething more than a mere change in the quantity of the preceſſion would be requiſite to ſolve this part of the phenomenon. Upon comparing the obſervations of ſtars near the ſolſtitial colure that were almoſt oppoſite to each other in right aſcenſion, they were found to be equally affected by this cauſe. For whilſt γ Draconis appeared to have moved northward, the ſmall ſtar, which is the 35th Camelopardali Hevelii in the Britiſh Catalogue, ſeemed to have gone as much towards the ſouth; which ſhewed, that this apparent motion in both thoſe ſtars might proceed from a nutation of the earth's axis; whereas the compariſon of the doctor's obſervations of the ſame ſtars, formerly enabled him to draw a different concluſion with reſpect to the cauſe of the annual aberrations ariſing from the motion of light. For the apparent alteration in γ Draconis, from that cauſe, being as great again as in the other ſmall ſtar, proved that that did not proceed from a nutation of the earth's axis; as, on the contrary, this may. Upon making the like compariſon between the obſervation of other ſtars that lie nearly oppoſite in right aſcenſion, whatever their ſituations were with reſpect to the cardinal points of the equator, it appeared that their change of declination was nearly equal, but contrary; and ſuch as a nutation or motion of the earth's axis would effect.

The moon's aſcending node being got back towards the beginning of Capricorn in the year 1732, the ſtars near the noctial colure appeared about that time to change their no more than a preceſſion of 50″ required; thoſe near the ſolſtitial colure altered theirs ear leſs than they ought. Soon after, the annual change of declination of the former was perceived to be diminiſhed, ſo as to become leſs than 50″ of preceſſion would cauſe; and it continued to diminiſh till the year 1736, when the moon's aſcending node was about the beginning of Libra, and her orbit had the leaſt inclination to the equator. But by this time, ſome of the ſtars near the ſolſtitial colure had altered their declinations 18″ leſs ſince the year 1727, than they ought to have done from a preceſſion of 50″. For γ Draconis, which in thoſe nine years would have gone about 8″ more ſoutherly, was obſerved, in 1736, to appear 10″ more northerly than it did in the year 1727.

As this appearance in γ Draconis indicated a diminution of the inclination of the earth's axis to the plane of the ecliptic, and as ſeveral aſtronomers have ſuppoſed that inclination to diminiſh regularly; if this phenomenon depended upon ſuch a cauſe, and amounted to 18″ in nine years, the obliquity of the ecliptic would, at that rate, alter a whole minute in thirty years; which is much faſter than any obſervations before made would allow. The doctor had therefore reaſon to think, that ſome part of this motion at leaſt, if not the whole, was owing to the moon's action upon the equatorial parts of the earth, which, he conceived, might cauſe a libratory motion of the earth's axis. But as he was unable to judge, from only nine years' obſervations, whether the axis would entirely recover the ſame poſition that it had in the year 1727, he found it neceſſary to continue his obſervations through a whole period of the moon's nodes; at the end of which he had the ſatisfaction to ſee, that the ſtars returned into the ſame poſitions again, as if there had been no alteration at all in the inclination of the earth's axis, which fully convinced him that he had gueſſed rightly as to the cauſe of the phenomenon. This circumſtance proves likewiſe, that if there be a gradual diminution of the obliquity of the ecliptic, it does not ariſe only from an alteration in the poſition of the earth's axis, but rather from ſome change in the plane of the ecliptic itſelf; becauſe the ſtars, at the end of the period of the moon's nodes, appeared in the ſame places, with reſpect to the equator, as they ought to have done if the earth's axis had retained the ſame inclination to an invariable plane.

The doctor having communicated theſe obſervations, and his ſuſpicion of their cauſe, to the late Mr. Machin, that excellent geometer ſoon after ſent him a table, containing the quantity of the annual preceſſion in the various poſitions of the moon's nodes, as alſo the correſponding nutations of the earth's axis; which was computed upon the ſuppoſition that the mean annual preceſſion is 50″, and that the whole is governed by the pole of the moon's orbit only; and, therefore, Mr. Machin imagined, that the numbers in the table would be too large, as, in fact, they were found to be. But it appeared that the changes which Dr. Bradley had obſerved, both in the annual preceſſion and nutation, kept the ſame law, as to increaſing and decreaſing, with the numbers of Mr. Machin's table. Thoſe were calculated upon the ſuppoſition, that the pole of the equator, during a period of the moon's nodes, moved round in the periphery of a little circle, whoſe centre was 23° 29′ diſtant from the pole of the ecliptic; having itſelf alſo an angular motion of 50″ in a year about the ſame pole. The north pole of the equator was conceived to be in that part of the ſmall circle which is fartheſt from the north pole of the ecliptic, at the time when the moon's aſcending node is in the beginning of Aries; and in the oppoſite point of it, when the ſame node is in Libra.

If the diameter of the little circle, in which the pole of the equator moves, be ſuppoſed equal to 18″, which is the whole quantity of the *nutation*, (which ſee,) as collected from

Dr. Bradley's obſervations of the ſtar γ Draconis, then all the phenomena of the ſeveral ſtars which he obſerved will be very nearly ſolved by his hypotheſis. But for the particulars of his ſolution, and the application of his theory to the practice of aſtronomy, we muſt refer to the excellent author himſelf, our intention being only to give the hiſtory of the invention.

The corrections ariſing from the aberration of light, and from the nutation of the earth's axis, muſt not be neglected in aſtronomical obſervations; ſince ſuch neglects might produce errors of near a minute in the polar diſtances of ſome ſtars.

As to the allowance to be made for the aberration of light, Dr. Bradley aſſures us, that having again examined thoſe of his own obſervations, which were moſt proper to determine the tranſverſe axis of the ellipſis which each ſtar ſeems to deſcribe, he found it to be neareſt to 40″; and this is the number he makes uſe of in his computations relating to the nutation.

Dr. Bradley ſays, in general, that experience has taught him, that the obſervations of ſuch ſtars as lie neareſt the zenith, generally agree beſt with one another, and are therefore the fitteſt to prove the truth of any hypotheſis. Phil. Tranſ. No. 485. vol. xlv. p. 1, &c.

Monſieur d'Alembert has publiſhed a treatiſe, entitled "Recherches ſur la Preceſſion des Equinoxes et ſur la Nutation de la Terre dans le Syſtème Newtonien," 4to. Paris, 1749. The calculations of this learned gentleman agree, in general, with Dr. Bradley's obſervations. But Monſieur d'Alembert finds, that the pole of the equator deſcribes an ellipſis in the heavens, the ratio of whoſe axes is as 4 to 3; whereas, according to Dr. Bradley, the curve deſcribed is either a circle or an ellipſis, the ratio of whoſe axes is as 18 to 16.

From this digreſſion we ſhall return to the proper motion of the ſtars and ſolar ſyſtem. This motion was firſt obſerved, as we have already ſuggeſted, by Dr. Halley, and afterwards by Le Monnier and Caſſini. Tobias Mayer had the merit of giving the firſt explanation of this proper motion; he compared the places of about eighty ſtars, as determined by Roemer, with his own obſervations, and he found that the greater number of them had a proper motion. He was apprized that this change of place in the poſition of the ſtars might be explained by a progreſſive motion of the ſun towards one quarter of the heavens; but the reſult of his obſervations not according with this hypotheſis, he concluded, that many centuries might elapſe before the true cauſe of this motion is explained. The poſſibility of a ſolar motion was ſuggeſted, upon theoretical principles, by the late Dr. Wilſon of Glaſgow; and M. de la Lande deduced the ſame opinion from the rotatory motion of the ſun; but another kind of argument has completely confirmed theſe conjectures.

If the ſun has a motion in abſolute ſpace, directed towards any quarter of the heavens, it is obvious that the ſtars in that quarter muſt appear to recede from each other, while thoſe in the oppoſite region ſeem gradually approaching. The proper motion of the ſtars, therefore, in thoſe oppoſite regions, as aſcertained by a compariſon of ancient with modern obſervations, ought to correſpond with this hypotheſis.

Dr. Herſchel has examined this ſubject with his uſual ſucceſs, and he has certainly diſcovered the direction in which our ſyſtem is gradually advancing. He found that the apparent proper motions of about forty-four ſtars out of fifty-ſix are very nearly in the direction which ſhould reſult from a motion of the ſun towards the conſtellation Hercules, or, more accurately, to a point in the heavens, whoſe right aſcenſion is 250° 52′·30″, and whoſe north polar diſtance is 40° 22′.

Dr. Herſchel, in eſtabliſhing this motion of the ſtarry and ſolar ſyſtems, begins with principles drawn from the theory of attraction, which evidently oppoſe every idea of abſolute reſt in any one of the ſtars, when once it is known that ſome of them are in motion; for the change that muſt ariſe by ſuch motion, in the value of a power which acts inverſely as the ſquares of the diſtances, muſt be felt in all the neighbouring ſtars; and if theſe be influenced by the motion of the former, they will again affect thoſe that are next to them, and ſo on till all are in motion. Now as we know that ſeveral ſtars, in divers parts of the heavens, do actually change their place, it will follow, that the motion of our ſolar ſyſtem is not a mere hypotheſis; and this conſideration will be confirmed by the reaſons that induce us to ſuppoſe, that moſt of thoſe very ſtars which have been obſerved to move, to be ſuch as are neareſt to us; and, therefore, their influence on our ſituation would of itſelf be a powerful argument in favour of the proper motion of the ſun, if it had been originally at reſt. Moreover, it ſeems very natural, that the changes which are obſerved to take place among the ſtars; ſuch as the increaſe of magnitude in many, and the gradual diſappearance of others; the periods of ſome not before obſerved, and the diſtances of many that are actually changing, while many more are ſuſpected to have a conſiderable motion; afford a ſtrong ſuſpicion that moſt probably every ſtar in the heavens is more or leſs in motion. Allowing the proper motion of the ſtars, it muſt follow, that our ſyſtem, with all its planets and comets, that is, the ſolar ſyſtem, is not leſs liable to ſuch a general agitation as is found to obtain among all the other celeſtial bodies. Aſtronomers have already obſerved what they call a proper motion in ſeveral of the fixed ſtars, and the ſame may be ſuppoſed of them all. We ought, therefore, to reſolve that which is common to all the ſtars, which are found to have what has been called a proper motion, into a ſingle real motion of the ſolar ſyſtem, as far as that will anſwer the known facts, and only to attribute to the proper motion of each particular ſtar the deviations from the general law the ſtars ſeem to follow in thoſe movements.

By Dr. Maſkelyne's account of the proper motion of ſome principal ſtars, we find that Sirius, Caſtor, Procyon, Pollux, Regulus, Arcturus, and α Aquilæ, appear to have reſpectively the following proper motions in right aſcenſion; − 0″.63; − 0″.28; − 0″.80; − 0″.93; − 0″.41; − 1″.40; and + 0″.57; and two of them, Sirius and Arcturus, in declination, *viz.* 1″.20 and 2″.01, both ſouthward.

Since the apparent motions of theſe ſeven ſtars may be accounted for, either by ſuppoſing them to move juſt as they appear to do, or elſe by ſuppoſing the ſun alone to have a motion in a direction ſuch as Dr. Herſchel aſſigns to it, we are no more authoriſed to ſuppoſe the ſun at reſt than we ſhould be to deny the diurnal motion of the earth, except in this reſpect, that the proofs of the latter are very numerous, whereas the former reſts only on a few though capital teſtimonies. Our author finds from other conſiderations, founded on a table by M. de la Lande of the proper motion of twelve ſtars, both in right aſcenſion and declination, for fifty years, (Phil. Tranſ. vol. lxxiii. p. 270, &c.), that this motion of the ſun, or ſolar ſyſtem, is directed towards the ſtar λ Herculis; and he mentions ſome very ſtriking circumſtances in the quantities of the real proper motions of the ſtars that deſerve notice. Firſt, Arcturus and Sirius being the largeſt of the ſtars, and therefore probably the neareſt, ought to have the moſt apparent motion, both in right aſcenſion and declination, which is agreeable to obſervation. Next, in regard to the right aſcenſion only, Arcturus being better ſituated to ſhew its motion, ought to have it much larger, which we find it has. Aldebaran, both badly ſituated and conſiderably ſmaller than the two former, ought to ſhew but little motion. Procyon, better ſituated than Sirius, though not quite ſo large, ſhould have almoſt as much motion; for, on ſuppoſing it farther off becauſe it appears ſmaller, the effect of the ſun's motion will be leſſened upon it; whereas, on the other hand, its better ſituation will partly compenſate for its greater diſtance. ι Cygni, very favourably ſituated, though but a ſmall ſtar, ſhould ſhew it conſiderably as well as α Aquilæ; whereas β Cygni ſhould have but little motion; and γ Piſcium, beſt ſituated of all, ſhould have a great increaſe of right aſcenſion.

In the laſt place, a very ſtriking agreement with the hypotheſis is diſplayed in Caſtor and Pollux. They are both pretty well ſituated; and we accordingly find that Pollux, for the ſize of the ſtar, ſhews as much motion in right aſcenſion as we could expect: but it is remarkable, and ſeemingly contrary to our hypotheſis, that Caſtor, equally well placed, ſhews no more than one half of the motion of Pollux. Now, if we recollect that the former is a double ſtar, conſiſting of two ſtars not much different in ſize, we can allow but about half the light to each of them, which affords a ſtrong preſumption of their being at a greater diſtance, and therefore their partial ſyſtematical parallax ought to be ſo much leſs than that of Pollux, which agrees wonderfully with obſervation. Not to mention the great difficulty in which we ſhould be involved, were we to ſuppoſe the motion of Caſtor to be really in the ſtar; for how extraordinary muſt appear the concurrence, that two ſtars, namely, thoſe that make up this apparently ſingle ſtar, ſhould both have a proper motion ſo exactly alike, that in all our obſervations hitherto they have not been found to diſagree a ſingle ſecond, either in right aſcenſion or declination, for fifty years together! Does not this ſeem ſtrongly to point out the common cauſe, the motion of the ſolar ſyſtem?

As to the quantity of the ſolar motion, Dr. Herſchel ſuggeſts the following hints. From the annual parallax of the fixed ſtars, which, from obſervations, he finds much leſs than it has hitherto been proved to be, we may certainly admit, that the diameter of the earth's orbit, at the diſtance of Sirius or Arcturus, would not nearly ſubtend an angle of one ſecond; but the apparent motion of Arcturus, if owing to a tranſlation of the ſolar ſyſtem, amounts to no leſs than 2″.7 a-year, as will appear if we compound the two motions of 1′ 11″ in right aſcenſion, and 1′ 55″ in declination, into one ſingle motion, and reduce it to an annual quantity. Hence we may, in a general way, eſtimate, that the ſolar motion can certainly not be leſs than that which the earth has in her annual orbit.

By conſidering the motion of the ſatellites round their primary planets, and of the primary planets round the ſun, Dr. Herſchel is led to ſuppoſe that the proper motion of the ſun is not rectilineal, but that it is performed round ſome diſtant and unknown centre. Although we may not acquieſce in the hypotheſis, that there is any immenſe central body of ſufficient magnitude to carry round it all the ſyſtems with which aſtronomers have filled the regions of ſpace, yet we may ſuppoſe, with M. de la Lande, that there is a kind of equilibrium among all the ſyſtems of the world, and that they have all a periodical circulation round their common centre of gravity. See Phil. Tranſ. vol. xcv. p. 233—256. Lalande's Aſtron. tom. iii.

The following table contains the proper motion of 36 of the principal fixed ſtars in right aſcenſion and declination, according to the accurate obſervations of Dr. Maſkelyne.

Table of the Annual Proper Motion of 36 Stars in Right Aſcenſion and Declination.

To learn to know the ſeveral fixed ſtars by the globe, ſee Globe.

The parallax and diſtance of the fixed ſtars, ſee under Parallax and Distance.

Stars, *Circumpolar*. See Circumpolar.

Star, *Falling*, in *Meteorology*, a meteor, the explication of which has puzzled all philoſophers, till our modern diſcoveries in electricity have led to the moſt probable account of it. Signor Beccaria makes it pretty evident, that it is an electrical appearance, and in proof of this poſition he recites the following fact. About an hour after ſunſet, he, and ſome friends that were with him, obſerved a falling ſtar directing its courſe towards them, and apparently growing larger and larger, but it diſappeared not far from them; when it left their faces, hands, and clothes, with the earth, and all the neighbouring objects, ſuddenly illuminated with a diffuſed and lambent light, attended with no noiſe at all. During their ſurprize at this appearance, a ſervant informed them that he had ſeen a light ſhine ſuddenly in the garden, and eſpecially upon the ſtream which he was throwing to water it. All theſe appearances were evidently electrical; and S. Beccaria was confirmed in his conjecture, that electricity was the cauſe of them, by the quantity of electric matter which he had ſeen gradually advancing towards his kite, which had very much the appearance of a falling ſtar. Sometimes alſo he ſaw a kind of glory round the kite, which followed it when it changed its place, but left ſome light, for a ſmall ſpace of time, in the place which it had quitted. Prieſtl. Elect. vol. i. p. 434. 8vo. See Ignis *Fatuus*.

Star, *Morning*. See Morning.

Star, *Place of a*. See Place.

Star, *Pole*. See Pole.

Stars, *Twinkling of the*. See Twinkling.

Stars, *Unformed*. See Informes.

Star, in *Electricity*, denotes the appearance of the electric matter on a point into which it enters. Beccaria ſuppoſes that the ſtar is occaſioned by the difficulty with which the electric fluid is extricated from the air, which is an electric. See Brush.

Star, in *Fortification*, a little fort, with five or more points, or ſaliant and re-entering angles, flanking one another, and their faces 90 or 100 feet long.

Formerly, ſtar-forts were frequently made in lines of circumvallation, after two or three redoubts. See Redoubt and Sconce.

Star, in *Heraldry*, denotes a charge frequently borne on the ſhield, and the honourable ordinaries, in the figure of a ſtar. It differs from the mullet, or ſpur-rowel, in that it is not pierced as this laſt is.

It uſually conſiſts of five rays or ſpokes. When it has ſix or eight, as among the Germans and Italians, particular mention muſt be made of them in blazoning.

Stars, on *Medals*, are marks of conſecration and deification, being intended as ſymbols of eternity. F. Joubert ſays, they ſometimes expreſs the children of princes reigning, and ſometimes the children dead; and placed in the rank of deities.

Star, in the *Manege*. *White ſtars in the forehead* are eſteemed good marks in all horſes, except white and grey ones: where nature fails to produce this good criterion, our jockies have frequently recourſe to art. See Horse.

The method of making ſtars, practiſed among the Dutch, is to roaſt a large onion in hot aſhes, and when near thoroughly done, to divide it in two, and dip it in ſcalding hot walnut-oil. This done, they immediately apply the flat ſide of it to the place the ſtar is to be on, and keep it there half an hour. After taking it off, they anoint the ſcalded place with ointment of roſes; in a ſhort time, the ſcarf-ſkin falls off, and white hair grows up in its room; but the middle always continues bare of hair, which is the certain characteriſtic of an artificial ſtar.

The method moſt uſed among us is to ſhave the hair from the place it is to be made on; then to apply a little oil of vitriol with a feather, or the like, paſſing it lightly over the bald place. This eats away the roots of the former hair, which will be ſucceeded by white. The ſore is healed up with copperas, and green ointment.

Star, *To make a Black*, on a white or other coloured horſe, waſh the place to be changed frequently with fern-roots and ſage, boiled in ley; and they ſay it will breed black hairs. The ſame may be done by beating ſour milk, galls, and ruſt, together, and anointing the part with it.

Star, *A Red*, is made with an ounce of aqua fortis, a penny-worth of aqua vitæ, and ſilver to the value of eighteen-pence, all heated together in a glaſs, and the place anointed with it. This immediately turns the hair to a perfect red; but it laſts no longer than till the horſe caſts his coat.

Star, or *Starr*, *Starrum*, in our *Old Writers*. All the deeds, obligations, &c. of the Jews, were called *ſtarra*, and writ for the moſt part in Hebrew alone, or in Hebrew and Latin; one of which yet remains in the treaſury of the exchequer, written in Hebrew without points, the ſubſtance of which is expreſſed in Latin juſt under it, like an Engliſh condition under a Latin obligation: this bears date in the reign of king John; and many ſtarrs, as well of grant and releaſe, as obligatory and by way of mortgage, are pleaded and recited at large in the Plea Rolls.

Before the baniſhment of the Jews under Edward I., their contracts and obligations were denominated *ſtarra*, or ſtarrs; which, by an ordinance of Richard I., preſerved by Hoveden, were commanded to be enrolled and depoſited in cheſts, under three keys, in certain places; one and the moſt conſiderable of which was in the king's exchequer, at Weſtminſter; and no ſtarr was allowed to be valid, unleſs it were found in ſome of the ſaid repoſitories.

The word ſtarr is a contraction from the Hebrew *ſchetar*; a deed or contract.

Star, in *Pyrotechny*, a compoſition of combuſtible matters; which being borne, or thrown aloft into the air, exhibits the appearance of a real ſtar.

Stars are generally uſed as appendages to rockets, a number of them being uſually encloſed in a conical cap, or cover, at the head of the rocket, and carried up with it to its utmoſt altitude, where the ſtars taking fire, are ſpread around, and exhibit an agreeable ſpectacle. For their compoſition, ſee Pyrotechny.

Star is alſo a badge of the orders of the Garter and Bath.

Star, *Order of the*, or *Our Lady of the Star*, an order of knighthood, inſtituted by king John II. of France in the year 1351, in imitation of the order of the Garter, not many years before eſtabliſhed in England by king Edward III., ſo denominated from a ſtar they wore on the ſtomach.

At firſt there were but thirty knights; but the order, in time, became depreciated by the multitude of perſons admitted without any diſtinction. For which reaſon Charles VII. when grand-maſter thereof, quitted it, and gave it the chevalier de Guet, knight of the watch at Paris, and his archers; who ſtill wear a ſtar on their coats. But this account is contradicted by others; who will have the order inſtituted by king Robert, in 1022, in honour of the Holy Virgin, and to have fallen in diſregard during the wars of Philip de Valois.

Others ſay, that Lewis XI. having inſtituted the order of St. Michael, this order was aboliſhed by his ſon Charles VIII.

The enſign of this order was the four capital letters M. R. A. V., embroidered in gold within a ſquare on the left breaſt of the knight's garment; between the letters a mullet of eight points, the point in baſe wavy, and larger than the other; over the mullet a crown, compoſed of fleurs-de-lis and balls. The collar was three rows of gold chains; thereon roſes enamelled white and red, and placed alternately.

Juſtiniani mentions another order of the Star, at Meſſina, in Sicily, called alſo the *order of the Creſcent*. This was inſtituted in the year 1268, by Charles of Anjou, brother of St. Louis, king of the Two Sicilies.

According to others, this order was inſtituted in 1351, when the princes of the houſe of Anjou being driven out of the kingdom of Naples, and Sicily falling again under the dominion of the kings of Aragon, this order, it is ſaid, was eſtabliſhed in lieu of that of the Creſcent, which was then aboliſhed, as is this order alſo. The badge of the order was a ſtar of eight points, ſurmounted with a mullet of eight points.

Others will have it inſtituted in 1464, by Renatus, duke of Anjou, who took the title of king of Sicily. At leaſt it appears, from the arms of this prince, that he made ſome alteration in the collar of the order; for, inſtead of fleurs-de-lis, and ſtars, he only bore two chains, whence hung a creſcent, with the old French word *loz;* which, in the language of rebus, ſignified *loz in a creſcent*.

The order, being ſunk into obſcurity, was raiſed again by the people of Meſſina, under the name of the "Noble Academy of the Knights of the Star," reducing the ancient collar to a ſingle ſtar, placed on a forked croſs; and the number of knights to ſixty-two. Their device was MONSTRANT REGIBUS ASTRA VIAM: which they expreſſed by
MR
the four initial letters * with the ſtar in the middle.

Star, *Order of the Polar*. See Polar.

Star *of Alexandria*, in *Botany*. See Ornithogalum.

Star-*Apple*. See Chrysophyllum.

Star-*Flower*. See Ornithogalum.

Star-*Hyacinth*. See Scilla.

Star *of Bethlehem*. See Ornithogalum.

Star *of the Earth*, the name of a plant famous for its virtues in curing the bite of a mad dog. The original account of its nature and virtues ſeems to be this: king James ſent to the Royal Society a dried ſpecimen of a plant, which had been ſent to him as the plant with which his dogs had been cured when bitten by a mad dog, and the name by which this was called was *ſtar of the earth*.

This plant was ſo ill dried, that it was not eaſily diſtinguiſhed; but at length Mr. Ray found it to be the *ſeſamoides ſalamanticum magnum*. It does not ſeem, however, clear, that this was the plant vulgarly known by that name, but rather that it was gathered by ſome ignorant perſon; neither the name ſtar of the earth at all agreeing with it, nor any account having been given before of its having ſuch virtues. Dr. Grey, in his Complete Farrier, greatly recommends the ſtar of the earth in the cure of this bite, and the plant he means is plainly the coronopus, or buck's-horn-plantain; and, upon the whole, it ſeems that this laſt mentioned is the plant properly called by this name, as its virtues have always been celebrated even in this caſe, and its leaves always are diſpoſed on the earth in the form of the rays of a ſtar. It is to be added to this, that the counteſs of Suffolk's powder, ſo famous in many places for this terrible diſeaſe, and by which ſeveral perſons have been known to be cured, is principally compoſed of this plant. Phil. Tranſ. N° 450. p. 155.

Star-*Fiſh*, called alſo the *Sea-ſtar*, in *Ichthyology*, is the general name for the Linnæan genus Asterias; under which term the ſeveral ſpecies are enumerated without deſcription. There are more than forty ſpecies, ſeparated into ſections, according as the individuals are lunate, ſtellate, or radiate.

A. *Lunate.*

Species.

Nobilis. Granulous, with a ridge round the margin, the diſk of which is glabrous. It is found in the North ſeas.

Pulvillus. Lubricous, with an entire ſimple margin. This is found in the North ſeas. It is deſcribed as having a body convex above, covered with a ſmooth ſanguineous ſkin tranſverſely in particular parts; beſet towards the margin with ſoft obtuſe white ſpines, about the ſize of a grain of millet-ſeed, and divided into ten areæ; the margin is not articulate, but rough in the angles, with about ten acute papillæ; beneath, the body is concave, ſmooth, whitiſh, with a roſy tinge, and hollowed by five grooves each ſide, covered with horizontal batons. It tinges warm water with a tawny colour.

Militaris. Every where granulous, with a granulous margin. It is found in the North ſeas.

Luna. Orbicular, entire. It inhabits India. The body is compreſſed, and every where ſprinkled with raiſed dots.

B. *Stellate.*

* Papposa. This ſpecies has from twelve to fourteen rays, the edges of which are ſurrounded with ſhort faſcicular proceſſes; the ſurface is muricate. It inhabits the European and Aſiatic ſeas. The body above is ferruginous, the diſk ſpotted with white; the rays are paler at the ends; beneath whitiſh, with paler papillæ and black grooves down the rays; the diſk is tinged with red; the rays are from 11 to 15; it is lanceolate, and a little convex above.

Spongiosa. This ſpecies is roughiſh; with five ſemicylindrical obtuſe rays, unarmed at the edges. It inhabits the Greenland ſeas, and is not three-quarters of an inch in diameter. The body is of a pale reddiſh, with a very minute and red central protuberance above, and rough, with minute crowded ſpines; the rays are inflected at the edges.

* Rubens. Lax, with five lanceolate, convex rays, covered above with ſingle ſpines, diſpoſed in rows. This is the Aſterias hiſpida of Pennant. It inhabits the ocean, and is from nine to fourteen inches in diameter. The body above is red, pale orange, yellowiſh, cinereous or black, ſometimes violet; it has from four to ſix rays, with four rows of papillæ beneath; the tubercles are ſometimes ſcattered, or diſpoſed in rows. In ſome of the individuals there are no prickles, and in ſome no briſtles.

* Seposita. With five round rays, reticulate beneath, and covered above with pectinate prickles. This is the Aſterias ſpinoſa of Pennant. It is very ſmall, and found in the European ſeas.

Endeca. With nine rays, every where covered with pectinate prickles. There is a variety of this ſpecies. It is found in the North ſeas; and the rays are from five to nine.

Minuta. With ſix rays, the edges with diſtant, projecting, faſcicular proceſſes. It inhabits the Northern ſeas. The body is of a pale yellow; about two lines and a half in diameter; and flat on each ſide.

* Glacialis. With five angular rays, the angles with prickly protuberances. It inhabits the North ſeas, and feeds on oyſters. The rays are thick and lanceolate. The body, when alive, is rufous, undulate with white, ſometimes cinereous brown, or green; the diſk above with tubercles diſpoſed in a circle, beneath hollow: the tentacula are numerous, pellucid, with a row of ſmall pinnules on each ſide; the back is marked with a round ſtriate operculum or lid.

* Clathrata. With five ſhort thick rays; hirſute beneath, and cancelled above. It inhabits the European ſeas; and is deſcribed and figured in Pennant's Britiſh Zoology.

Echinites. With twenty rays, each with two rows of ſuckers, and numerous large and ſmall moveable ſpines. It inhabits Batavia. The diſk as well as the rays are covered with ſmall moveable ſpines.

Reticulata. Rays four, reticulate with prickles. It is found in the Indian ſeas.

Phrygiana. This ſpecies is every where beſet with papillæ, which are beneath of a roſy colour. It is found on the coaſts of Norway.

Nodosa. With five convex rays, longitudinally elevated, and muricate: it is met with on the coaſts of the Indian ſeas.

* Violacea. Lax, with a grey-brown ſurface, and violet tubercles; it has five rays. Inhabits the European and Northern ſeas. The body has ſometimes a violet ſurface, and marked ſometimes with violet tubercles only; theſe are either diſpoſed in rows, or irregularly ſcattered; the diſk is orbicular; the rays lanceolate and reddiſh at the tip; beneath yellowiſh in the grooves.

Sanguinolenta. Above ſanguineous; the rays are tipt with white. It inhabits the North ſeas.

Perforata. Unarmed; with perforated dots on the back. This alſo is an inhabitant of the North ſeas.

Aranciaca. Diſk broad; rays five, ſub-depreſſed, and prickly at the margins: in the Mediterranean and North ſeas.

* Equestris. Five rays; diſk reticulate, and perforated with dots; tubercles five; margin ſub-articulate; beneath a ſingle row of tentacula: an European ſpecies.

Lævigata. With five ſemi-cylindrical, obtuſely eight-angled, unarmed rays. It inhabits the Mediterranean and Indian ſeas. The rays are covered with obſolete warts, and between them, at the ſides, are hollow dots; beneath, the warts are diſpoſed in quincunx.

* Membranacea. With five broad membranaceous rays, extremely thin and flat. Inhabits the European and Mediterranean ſeas. The rays are rough, with tubercles; beneath with five elevated convex ribs.

Granulosa. Pentangular, unarmed, each ſide teſſellate with granulations, the margin is jointed. It is found on the coaſts of the iſland of Santa Cruz.

C. *Radiate.*

Rosea. Rough, with reticulate granulations; rays round. This ſpecies is found in the Belgic and Norway ſeas, and is reckoned extremely elegant. Body above of a rich roſe-colour, ſometimes inclining to orange, with blackiſh dots between the granulations; beneath whitiſh, with dilated grooves; a quadruple row of tentaculæ, and five rows of divergent pinnules; rays white at the tip.

Pertusa. Rough, rays round, with a narrow, gibbous baſe. This inhabits the North ſeas.

* Ophiura. Diſk ſcaly; ſcale of the angles ſerrate. It inhabits the ocean, is very ſmall, and moves ſlowly. The body above is generally grey, reddiſh, or violet, rarely white; glabrous, with five rays; the diſk is orbicular; the rays are four times as long as the body, ſlender, quadrangular, flexuous, and covered with a ſingle row of ſcales. It has been aſſumed, rather than proved, that the miſchievous effects which at certain times of the year are produced by eating the common muſcle, are occaſioned by their having fed upon this ſpecies of aſterias.

Aculeata. With glabrous prickles; it is ſhorter than the diameter of the rays. It inhabits the ocean. It has five rays. The body varies in colour; it is in ſhape orbicular, with minute ſcales beneath, ſix of which reſemble a corol.

Ciliaris. With rough ſpines, longer than the diameter of the rays. It inhabits the Indian and North ſeas.

* Sphærulata. With five ſlender-jointed rays, hirſute on the ſides; with a ſmall globular head between the baſe of each ray. It inhabits the European ſeas. The body is pentangular, indented, ſmooth above the aperture, beneath it is five-pointed.

* Pentaphylla. This ſpecies is known by five ſlender rays, hirſute at the ſides, and teſſellate above, and below green, ſometimes with ſky-blue. It inhabits the Britiſh coaſts. The body is regularly pentangular.

* Varia. With five hirſute rays, annulate with red; the body is circular, with ten radiate ſtreaks; the ends are lozenge-form. This alſo is found on our own coaſts, as are the four that follow.

* Aculearis. This ſpecies is known by its five ſlender, hirſute rays; the body is round, with alternately broad and narrow ſtreaks from the centre.

* Hastata. With five hirſute, jointed rays; the body is pentagonal and indented, browniſh-red, with ten ochraceous ſtreaks, five ſlender, with javelin-ſhaped extremities.

* Fissa. With five ſlender, hirſute rays; the body is circular, with five equi-diſtant dents, penetrating deep into the ſides, and five light-coloured ſtreaks from the centre.

* Nigra. This alſo has five hirſute olive rays, teſſellate with deeper ſhades: the body is pentagonal, black, with five radiate ſtreaks of white.

Tenella. With ten pectinate rays above; and filiform ones beneath, which are thickened at the joints. It is found on the coaſts of Santa Cruz. The body is white; the ſtem of the rays is longer.

* Pectinata. With ten pectinate rays above, and fewer filiform ones beneath; the joints are equal; diſk ſmooth above. It inhabits the European and Indian ſeas. The body is covered above with five unequal valves; the colour is of a deep red; the filiform rays beneath are terminated by an incurved claw.

Multiradiata. This ſpecies has ten palmate, ſub-quadrifid, pectinate rays above, and numerous filiform ones beneath; the diſk is granulate: inhabits the Indian ocean.

* Caput Medusæ. With five divided and ſub-divided rays; diſk and rays granulate; mouth depreſſed. This ſpecies inhabits moſt ſeas, and is an extremely curious ſea-animal; the five rays dividing into two ſmaller ones, and each of theſe dividing again into two others; which mode of regular ſub-diviſion is continued to a vaſt extent, gradually decreaſing in ſize, till at length the ramifications amount to many thouſands, forming a beautiful net-work. Its colour is ſometimes pale or reddiſh-white, ſometimes brown.

Euryali. Rays divided and ſub-divided; diſk papillous, and with the rays granulate; the mouth is a little raiſed. It inhabits the Cape of Good Hope.

Oligœtes. Rays very long and ſimple, with two acute moveable ſtyles at each joint. Found near Curaſſoa, adhering to gorgoniæ. The body is pentangular, minute, ochraceous, and rather hard.

Nigrita. With five jointed rays, covered with imbricate ſcales above, and lateral patulous ramifications; the diſk is obtuſely pentangular and granulate.

TRICOLOR. With five jointed rays, pectinate at the ſides; the ramifications are rough; the diſk is hiſpid. It is found on the coaſt of the Feroe iſlands.

FRAGILIS. Diſk orbicular, muricate, ſpinous on the back: rays five, jointed and pectinate at the ſides; the ramifications ſerrato-muricate: found in the North ſeas.

The moſt frequent kind of ſtar-fiſh is that which has five rays, which iſſue in the manner of ſo many vermiform, or worm-like proceſſes: theſe therefore are called *ſtella vermiformes*, or the *worm-like* ſtar-fiſh. Another kind, nearly approaching to the nature of theſe, has more than five rays, and from the ſides of theſe other tranſverſe proceſſes are produced, which are covered with an extremely fine kind of down, or hairineſs; theſe are called the *hairy* ſtar-fiſh. A third kind is called the *aſtrophyta*, or *plant-like* ſtar-fiſh: this is compoſed of a body from whence there ariſe a great number of branches, which divaricating more and more, are at length increaſed, or divided into a prodigious number; and theſe being cylindric in figure, reſemble very much the branches of plants. Several of the ſpecies of the ſtar-fiſh are eatable, and ſome of them afford a very good nouriſhment. Some are preſcribed by phyſicians as ingredients in plaſters.

Every ray of the ſtar-fiſh is furniſhed with ſo very large a number of legs, that they cover the whole ſurface: they are diſpoſed in four ranges, each of which contains about ſeventy-four; ſo that the whole ray contains three hundred and four, and conſequently the fiſh has, upon all five of its rays, no leſs than fifteen hundred and twenty legs. With all this numerous train of legs, however, the animal moves but very ſlowly; and indeed they are ſo ſoft and feeble, that they ſcarcely deſerve the name of legs, and, more properly ſpeaking, they are only a ſort of horns, like thoſe of our garden-ſnails, but they ſerve the animal to walk with, and are therefore called legs. Mem. Acad. Par. 1710.

The amazing property of reproducing the eſſential parts, when loſt, extends to the ſtar-fiſh. M. Reaumur, on the diſcovery of this property in the polype, obſerved theſe other animals, as they lay on the ſhores of Poictou and other places, and often found that ſpecies of ſtar-fiſh which is very commonly known, and which has naturally five rays or arms, with only three or four, one or two being wanting; and on taking up and examining theſe mutilated ones, nature was always found reproducing the limb that was wanting; and on cutting and breaking other ſtar-fiſh into ſeveral parts, it was but a very little while before the broken parts cicatrized, and every part remained alive. Phil. Tranſ. N° 464. Append.

The *arboreſcent* ſtar-fiſh, *ſtella arboreſcens*, or *caput meduſæ* of Linnæus, is one of the curioſities of nature, found in ſeveral cabinets of natural rarities. See MEDUSÆ *Caput*, and *ſupra*. Grew, Muſ. Reg. Societ. part i. ſect. 5. cap. 4. p. 122.

This has been found in the north of Scotland, and on the coaſt of Cornwall. See BASKET-*Fiſh*.

STAR-*Gazer*, the Engliſh name of the uranoſcopus.

STAR-*Shot*, the common name of a gelatinous ſubſtance often found lying on the ſurface of the earth, and called by ſome *ſtar-jelly*, and *ſtar-fallen*.

The vulgar have been always of opinion, that this was produced from that meteor which they call a falling-ſtar; others have imagined it a vegetable ſubſtance, and ſuppoſed it grew out of the earth: but it is probably the half-digeſted food of herons, bitterns, crows, ſea-mews, and coddymoddies, principally when they have fed upon frogs or earth-worms.

The heads of frogs are found whole in maſſes of this matter, and alſo parts of worms: theſe birds, when ſhot, diſgorge a ſubſtance of the ſame kind. This is gelatinous, like a thick mucilage of gum tragacanth, and cold to the touch. In it are often yellow ſpecks and ſmall clots, like grumous blood. It ſmells like putrid fleſh, when kept, and is principally found in miſty mornings, and in wet weather, in autumn, winter, and ſpring. Moreton's Northampton, p. 353.

Mr. Boyle ſays, he has ſeen this jelly reſolved, by digeſtion only, into a permanent liquor, and that a phyſician of his acquaintance extolled it as a ſpecific, outwardly applied to wens. Works, Abr. vol. i. p. 310.

STAR-*Shot*, in *Artillery*, conſiſts of four pieces of iron, whoſe baſes, when ſeparate, form the quadrant of a circle; ſo that the whole being joined forms a cylinder equal to the ſhot of the cannon. Each of theſe pieces is furniſhed with an iron bar, the extremity of which is attached to a ſort of link, as keys are ſtrung upon a ring. Being diſcharged from the gun, the four branches or arms extend every way from the link in the centre. Theſe are uſed in the ſea-ſervice, and chiefly deſigned for deſtroying the ſails and rigging; but their flight and execution are very precarious at any conſiderable diſtance.

STAR-*Stone*, *Aſteria*, in *Natural Hiſtory*, the name of a kind of extraneous foſſil, of a very regular figure and ſtructure, and approaching very much to the nature of the entrochi, having the ſame ſubſtance and inner ſtructure, and being much of the ſame ſize, though different in form: it comprehends the *aſteropodia* and the *appendiculæ*, or wires of the aſteriæ. The aſteriæ are by many affirmed to be the foſſile radii of the ſtar-fiſh of the decempede, or ten-rayed kind: others have thought that ſome ſpecies of them have been the remains of the common coriaceous kinds. The encrinos, or lilium lapideum, ſeems to be a part of one of the ten-rayed kinds; and the trochitæ, and entrochi, are plainly owing to the fragments of ſeveral of theſe kinds. Linkius, de Stellis Marin.

Mr. Ellis has particularly deſcribed, and illuſtrated by figures, foſſils of this kind, as well as the animals or ſtar-fiſh to which they belong; but as the ſtem of the animal, the ſpecimen of which he examined, and from which his deſcription is taken, was broke off ſhort at the bottom, he is in doubt whether it moves about in the ſea, or is fixed to rocks and ſhells by a baſe, like corals, ſponges, and keratophytons. Phil. Tranſ. vol. lii. part i. art. 56.

The aſteropodia (ſee ASTEROPODIUM), in ſubſtance and inner ſtructure, agree perfectly with the ſhells of the echinitæ, found in our chalk-pits, and with the aſteriæ and entrochi; theſe bodies being all compoſed of obliquely-arranged plates of a tabulated ſpar: the ſeveral parts of which they are compoſed are all convex on one ſide, and concave on the other; but they are of very different ſhapes, being ſometimes roundiſh, ſometimes oblong, often quadrangular, and not unfrequently of different numbers of angles. They have frequently two, ſometimes more, ridges running acroſs them, and ſometimes they have tubercles, or ſmall protuberances, ſtanding either on their upper or under ſide: they are ſometimes found ſingle, but more frequently compound, or arranged into ſmaller or larger parcels, being placed over one another in the manner of the tiles of a houſe, and ſeem truly to have been originally part of an imbricated ſhell, or cruſt of ſome ſpecies of ſea-fiſh. They are in theſe compound maſſes even very evidently fragments, and are uſually of irregularly broken figures, though ſometimes they reſemble, in ſome degree, parts of the rays of one or other of the kinds of ſtar-fiſh. They are uſually found looſe from the aſteriæ, though lying among them; but ſometimes the aſteriæ are regularly fixed on them, juſt as the entrochi on the modioli, and are plainly ſeen to have originally grown out of them.

The aſteropodia ſeem properly the baſes of the aſteriæ, and the aſteriæ themſelves are branches of them. The aſteriæ are ſhort, and have commonly ſomewhat crooked angular columns, compoſed of ſeveral joints, each reſembling the figure of a radiated ſtar, with a greater or ſmaller number of rays in the different ſpecies: they are uſually found of about an inch in length, and of the thickneſs of a gooſe-quill. Some of them have five angles or rays, and others only four, and in ſome the angles are equidiſtant, while in others they are irregularly ſo; in ſome alſo they are ſhort and blunt, while in others they are long, narrow, and pointed; and ſome have their angles ſo very ſhort and obtuſe, that at firſt ſight they may be taken for entrocho-aſteriæ. The ſeveral joints in the ſame ſpecimen are uſually all of the ſame thickneſs; this, however, is not always the caſe, but in ſome they are larger at one end, and in others at the middle, than in any other part of the body; and ſome ſpecies have one of the rays bifid, ſo as to emulate the appearance of a ſix-rayed kind.

All the aſteriæ are naturally ſulcated between the angles, but this in a very different degree; ſome are very little ſo, while others are cut ſo deeply, that the ſingle joints of them reſemble the rowels of a ſpur. One end of the column is frequently found finely engraved along the edges of the angles, or rays, while the other end is ſmooth, or nearly ſo; and the ſame is often the caſe alſo in the ſingle joints. Not unfrequently, alſo, one end of a column is indented, and the other has five ſtriæ, running from a hollow centre to the ſulci between the rays. They are found of various ſizes and colours; the longeſt ſeldom arrive, however, at two inches; and they are found of all the intermediate bulk from this down to the length of a barley-corn: they are not unfrequently found, alſo, compreſſed and flattened, as is common to the foſſils that have been formed in animal moulds.

They are uſually bedded in ſtrata of clay, though not unfrequently in thoſe of a lax ſort of quarry-ſtone, and ſometimes in a harder. They uſually have ſea-ſhells, and other marine remains, lying about them; and ſometimes theſe ſhells adhere to the aſteriæ, and when ſeparated from them, do no injury to the aſteriæ, but themſelves ſhew a mark of the figure of the body, or part of the column, when a part has been always wanting in the ſhell.

From the columns of the aſteriæ there are ſometimes propagated certain ſmall branches, like thoſe of the entrochi; theſe are called by authors *appendiculæ aſteriarum*, or the wires of the aſteriæ. These are ſometimes two inches long, and the largeſt or thickeſt joint always adheres to the aſteria, all the ſucceeding ones growing ſmaller, and the branch more tapering toward the end. In their natural ſituation on the aſteria, they ſtand in regular circles at different diſtances one above another: there is always one wire in each of the ſulci, or channels of the body, and theſe ſtand evenly againſt one another.

Theſe wires or appendiculæ are very ſeldom, however, found in this their native ſtate, or fixed to the bodies of the aſteriæ; they are commonly found broken off, and lying looſe among them, either in fragments of different lengths, or in ſingle joints, immerſed in ſtone, or lying among the ſtrata of clay.

The aſteriæ may be reduced to two kinds; the firſt, thoſe whoſe whole bodies make the form of a ſtar; the ſecond, thoſe which in the whole are irregular, but which are adorned, as it were, with conſtellations in the parts.

Dr. Liſter, for diſtinction ſake, only gives the name *aſteria* to the former ſort, diſtinguiſhing the latter by the appellation of *aſtroites;* the other naturaliſts generally uſe the two indiſcriminately. The aſteria ſpoken of by the ancients appears to be of this latter kind.

The quality of moving in vinegar, as if animated, is ſcarcely perceivable in the aſtroites, but is ſignal in the aſteria. The former muſt be broken in ſmall pieces before it will move; but the latter will move, not only in a whole joint, but in two or three knit together. Plott, Nat. Hiſt. Oxford.
